# Package 'ISAnalytics'

March 30, 2021

**Title** Analyze gene therapy vector insertion sites data identified from genomics next generation sequencing reads for clonal tracking studies

**Version** 1.0.10

**Date** 2020-07-03

**Description** In gene therapy, stem cells are modified using viral vectors to deliver the therapeutic transgene and replace functional properties since the genetic modification is stable and inherited in all cell progeny. The retrieval and mapping of the sequences flanking the virus-host DNA junctions allows the identification of insertion sites (IS), essential for monitoring the evolution of genetically modified cells in vivo. A comprehensive toolkit for the analysis of IS is required to foster clonal trackign studies and supporting the assessment of safety and long term efficacy in vivo. This package is aimed at (1) supporting automation of IS workflow, (2) performing base and advance analysis for IS tracking (clonal abundance, clonal expansions and statistics for insertional mutagenesis, etc.), (3) providing basic biology insights of transduced stem cells in vivo.

# R **topics documented:**

| aggregate_metadata | *Performs aggregation on metadata contained in the association file.* |
|---|---|

## Description

[**Experimental**] Groups metadata by grouping_keys and returns a summary of info for each group.
For more details on how to use this function: `vignette("Working with aggregate functions",package = "ISAnalytics")`

## Usage

```
aggregate_metadata(
  association_file,
  grouping_keys = c("SubjectID", "CellMarker", "Tissue", "TimePoint"),
  import_stats = TRUE
)
```

## Arguments

association_file

The imported association file (via `import_association_file`)

grouping_keys    A character vector of column names to form a group

import_stats    Should Vispa2 stats files be imported and included?

## Value

A tibble

## See Also

Other Aggregate functions: `aggregate_values_by_key()`

## Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path_AF <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_correct <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root_correct <- unzip_file_system(root_correct, "fs")
association_file <- import_association_file(path_AF, root_correct,
    dates_format = "dmy"
)
aggregated_meta <- aggregate_metadata(association_file, import_stats = FALSE)
options(op)
```

---

```
aggregate_values_by_key
```
*Aggregates matrices values based on specified key.*

---

## Description

**[Experimental]** Performs aggregation on values contained in the integration matrices based on the key and the specified lambda. For more details on how to use this function: `vignette("Working with aggregate functions",package = "ISAnalytics")`

## Usage

```
aggregate_values_by_key(
  x,
  association_file,
  value_cols = "Value",
  key = c("SubjectID", "CellMarker", "Tissue", "TimePoint"),
  lambda = list(sum = ~sum(.x, na.rm = TRUE)),
  group = c(mandatory_IS_vars(), annotation_IS_vars())
)
```

## Arguments

| | |
|---|---|
| x | A single integration matrix (tibble) or a list of imported integration matrices (tibble) |
| association_file | |
| | The imported association file |
| value_cols | A character vector containing the names of the columns to apply the given lambdas. Must be numeric or integer columns. |
| key | A string or a character vector with column names of the association file to take as key |
| lambda | A named list of functions or purrr-style lambdas. See details section. |
| group | Other variables to include in the grouping besides key, can be set to NULL |

## Details

**Setting the lambda parameter:**

The lambda parameter should always contain a named list of either functions or purrr-style lambdas. It is also possible to specify the namespace of the function in both ways, for example:

```
lambda = list(sum = sum, desc = psych::describe)
```

Using purrr-style lambdas allows to specify arguments for the functions, keeping in mind that the first parameter should always be `.x`:

```
lambda = list(sum = ~sum(.x, na.rm = TRUE))
```

It is also possible to use custom user-defined functions, keeping in mind that the symbol will be evaluated in the calling environment, for example if the function is called in the global environment and lambda contains "foo" as a function, "foo" will be evaluated in the global environment.

```
foo <- function(x) {
  sum(x)
}

lambda = list(sum = ~sum(.x, na.rm = TRUE), foo = foo)

# Or with lambda notation
lambda = list(sum = ~sum(.x, na.rm = TRUE), foo = ~foo(.x))
```

**Constraints on aggregation functions:**

Functions passed in the lambda parameters must respect a few constraints to properly work and it's the user responsibility to ensure this.

- Functions have to accept as input a numeric or integer vector
- Function should return a single value or a list/data frame: if a list or a data frame is returned as a result, all the columns will be added to the final data frame.

### Value

A list of tibbles or a single tibble according to input

### See Also

Other Aggregate functions: [aggregate_metadata](#)()

### Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path_AF <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_correct <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root_correct <- unzip_file_system(root_correct, "fs")
association_file <- import_association_file(path_AF, root_correct,
    dates_format = "dmy"
)
matrices <- import_parallel_Vispa2Matrices_auto(
    association_file = association_file, root = NULL,
    quantification_type = c("fragmentEstimate", "seqCount"),
    matrix_type = "annotated", workers = 2, matching_opt = "ANY"
)
agg <- aggregate_values_by_key(
    x = matrices$seqCount,
    association_file = association_file
)
options(op)
```

---

annotation_IS_vars    *Names of the annotation variables for an integration matrix.*

---

### Description

Contains the names of the columns that are present if the integration matrix is annotated.

**Usage**

```
annotation_IS_vars()
```

**Value**

A character vector

**Examples**

```
annotation_IS_vars()
```

---

```
association_file_columns
                           Names of the columns in the association file.
```

---

**Description**

All the names of the columns present in the association file.

**Usage**

```
association_file_columns()
```

**Value**

A character vector

**Examples**

```
association_file_columns()
```

---

```
as_sparse_matrix          Converts tidy integration matrices in the original sparse matrix form.
```

---

**Description**

[**Maturing**] This function is particularly useful when a sparce matrix structure is needed by a specific function (mainly from other packages).

**Usage**

```
as_sparse_matrix(
  x,
  fragmentEstimate = "fragmentEstimate",
  seqCount = "seqCount",
  barcodeCount = "barcodeCount",
  cellCount = "cellCount",
  ShsCount = "ShsCount"
)
```

## Arguments

| | |
|---|---|
| x | A single tidy integration matrix or a list of integration matrices. Supports also multi-quantification matrices obtained via comparison_matrix |
| fragmentEstimate | |
| | For multi-quantification matrix support: the name of the fragment estimate values column |
| seqCount | For multi-quantification matrix support: the name of the sequence count values column |
| barcodeCount | For multi-quantification matrix support: the name of the barcode count values column |
| cellCount | For multi-quantification matrix support: the name of the cell count values column |
| ShsCount | For multi-quantification matrix support: the name of the Shs Count values column |

## Value

Depending on input, 2 possible outputs:

- A single sparce matrix (tibble) if input is a single quantification matrix

- A list of sparce matrices divided by quantification if input is a single multi-quantification matrix or a list of matrices

## See Also

Other Utility functions: generate_Vispa2_launch_AF(), generate_blank_association_file(), unzip_file_system()

## Examples

```
path <- system.file("extdata", "ex_annotated_ISMatrix.tsv.xz",
    package = "ISAnalytics"
)
matrix <- import_single_Vispa2Matrix(path)
sparse <- as_sparse_matrix(matrix)
```

---

CIS_grubbs                 *Grubbs test for Common Insertion Sites (CIS).*

---

## Description

**[Experimental]** Statistical approach for the validation of common insertion sites significance based on the comparison of the integration frequency at the CIS gene with respect to other genes contained in the surrounding genomic regions. For more details please refer to this paper: https://ashpublications.org/blood/article/117/20/5332/21206/Lentiviral-vector-common-integration-sites-

## Usage

```
CIS_grubbs(
   x,
  genomic_annotation_file = system.file("extdata", "hg19.refGene.oracle.tsv.xz",
     package = "ISAnalytics"),
  grubbs_flanking_gene_bp = 1e+05,
  threshold_alpha = 0.05,
  add_standard_padjust = TRUE
)
```

## Arguments

| | |
|---|---|
| x | An integration matrix, must include the `mandatory_IS_vars()` columns and the `annotation_IS_vars()` columns |
| genomic_annotation_file | |
| | Database file for gene annotation, see details |
| grubbs_flanking_gene_bp | |
| | Number of base pairs flanking a gene |
| threshold_alpha | |
| | Significance threshold |
| add_standard_padjust | |
| | Compute the standard padjust? |

## Details

### Genomic annotation file:

This file is a data base, or more simply a .tsv file to import, with genes annotation for the specific genome. The annotations for the human genome (hg19) is already included in this package. If for any reason the user is performing an analysis on another genome, this file needs to be changed respecting the USCS Genome Browser format, meaning the input file headers should be:

```
## name2, chrom, strand
##  min_txStart, max_txEnd, minmax_TxLen
##  average_TxLen, name, min_cdsStart
##  max_cdsEnd, minmax_CdsLen, average_CdsLen
```

## Value

A data frame

## See Also

Other Analysis functions: comparison_matrix(), compute_abundance(), cumulative_count_union(), sample_statistics(), separate_quant_matrices(), threshold_filter(), top_integrations()

## Examples

```
op <- options(ISAnalytics.widgets = FALSE)

path_AF <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_correct <- system.file("extdata", "fs.zip",
```

```
        package = "ISAnalytics"
    )
root_correct <- unzip_file_system(root_correct, "fs")

matrices <- import_parallel_Vispa2Matrices_auto(
    association_file = path_AF, root = root_correct,
    quantification_type = c("seqCount", "fragmentEstimate"),
    matrix_type = "annotated", workers = 2, patterns = NULL,
    matching_opt = "ANY",
    dates_format = "dmy"
)

cis <- CIS_grubbs(matrices$seqCount)

options(op)
```

---

CIS_volcano_plot          *Trace volcano plot for computed CIS data.*

---

#### Description

[Experimental] Traces a volcano plot for IS frequency and CIS results.

#### Usage

```
CIS_volcano_plot(
  x,
  onco_db_file = system.file("extdata", "201806_uniprot-Proto-oncogene.tsv.xz", package
    = "ISAnalytics"),
  tumor_suppressors_db_file = system.file("extdata",
    "201806_uniprot-Tumor-suppressor.tsv.xz", package = "ISAnalytics"),
  species = "human",
  known_onco = known_clinical_oncogenes(),
  suspicious_genes = clinical_relevant_suspicious_genes(),
  significance_threshold = 0.05,
  annotation_threshold_ontots = 0.1,
  facet_rows = NULL,
  facet_cols = NULL
)
```

#### Arguments

| | |
|---|---|
| x | Either a simple integration matrix or a data frame resulting from the call to [CIS_grubbs](#) with add_standard_padjust = TRUE |
| onco_db_file | Uniprot file for proto-oncogenes (see details) |
| tumor_suppressors_db_file | |
| | Uniprot file for tumor-suppressor genes |
| species | One between "human", "mouse" and "all" |
| known_onco | Data frame with known oncogenes. See details. |
| suspicious_genes | |
| | Data frame with clinical relevant suspicious genes. See details. |

significance_threshold
               The significance threshold

annotation_threshold_ontots
               Value above which genes are annotated

facet_rows     Column names to pass to the faceting function as rows (NULL for no faceting)

facet_cols     Column names to pass to the faceting function as columns (NULL for no faceting)

## Details

**Input data frame:**

Users can supply as x either a simple integration matrix or a data frame resulting from the call to
[CIS_grubbs](#) with add_standard_padjust = TRUE. In the first case an internal call to the function
CIS_grubbs is performed.

**Oncogene and tumor suppressor genes files:**

These files are included in the package for user convenience and are simply UniProt files with
gene annotations for human and mouse. For more details on how this files were generated use the
help ?filname function.

**Known oncogenes:**

The default values are contained in a data frame exported by this package, it can be accessed by
doing:

```
head(known_clinical_oncogenes())
```

```
## # A tibble: 5 x 2
##    GeneName KnownClonalExpansion
##    <chr>    <lgl>
## 1 MECOM     TRUE
## 2 CCND2     TRUE
## 3 TAL1      TRUE
## 4 LMO2      TRUE
## 5 HMGA2     TRUE
```

If the user wants to change this parameter the input data frame must preserve the column structure.
The same goes for the suspicious_genes parameter (DOIReference column is optional):

```
head(clinical_relevant_suspicious_genes())
```

```
## # A tibble: 6 x 3
##    GeneName ClinicalRelevance DOIReference
##    <chr>    <lgl>             <chr>
## 1 DNMT3A    TRUE              https://doi.org/10.1182/blood-2018-01-829937
## 2 TET2      TRUE              https://doi.org/10.1182/blood-2018-01-829937
## 3 ASXL1     TRUE              https://doi.org/10.1182/blood-2018-01-829937
## 4 JAK2      TRUE              https://doi.org/10.1182/blood-2018-01-829937
## 5 CBL       TRUE              https://doi.org/10.1182/blood-2018-01-829937
## 6 TP53      TRUE              https://doi.org/10.1182/blood-2018-01-829937
```

## Value

A plot

## Examples

```
op <- options(ISAnalytics.widgets = FALSE)

path_AF <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_correct <- system.file("extdata", "fs.zip",
    package = "ISAnalytics"
)
root_correct <- unzip_file_system(root_correct, "fs")

matrices <- import_parallel_Vispa2Matrices_auto(
    association_file = path_AF, root = root_correct,
    quantification_type = c("seqCount", "fragmentEstimate"),
    matrix_type = "annotated", workers = 2, patterns = NULL,
    matching_opt = "ANY",
    dates_format = "dmy"
)

cis <- CIS_grubbs(matrices$seqCount)
plot <- CIS_volcano_plot(cis)
options(op)
```

---

clinical_relevant_suspicious_genes
                        *Clinical relevant suspicious genes (for mouse and human).*

---

## Description

Clinical relevant suspicious genes (for mouse and human).

## Usage

```
clinical_relevant_suspicious_genes()
```

## Value

A data frame

## See Also

Other Plotting function helpers: known_clinical_oncogenes()

## Examples

```
clinical_relevant_suspicious_genes()
```

---

comparison_matrix          *obtain a single integration matrix from individual quantification matrices.*

---

### Description

[**Maturing**] Takes a list of integration matrices referring to different qunatification types and merges them in a single data frame that has multiple value columns, each renamed according to their quantification type of reference.

### Usage

```
comparison_matrix(
  x,
  fragmentEstimate = "fragmentEstimate",
  seqCount = "seqCount",
  barcodeCount = "barcodeCount",
  cellCount = "cellCount",
  ShsCount = "ShsCount"
)
```

### Arguments

| | |
|---|---|
| x | A named list of integration matrices, ideally obtained via import_parallel_Vispa2Matrices_interactive or import_parallel_Vispa2Matrices_auto. Names must be quantification types. |
| fragmentEstimate | |
| | The name of the output column for fragment estimate values |
| seqCount | The name of the output column for sequence count values |
| barcodeCount | The name of the output column for barcode count values |
| cellCount | The name of the output column for cell count values |
| ShsCount | The name of the output column for Shs count values |

### Value

A tibble

### See Also

quantification_types

Other Analysis functions: `CIS_grubbs()`, `compute_abundance()`, `cumulative_count_union()`, `sample_statistics()`, `separate_quant_matrices()`, `threshold_filter()`, `top_integrations()`

### Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
```

```
matrices <- import_parallel_Vispa2Matrices_auto(
    path, root,
    c("fragmentEstimate", "seqCount"), "annotated", 2, NULL, "ANY",
    dates_format = "dmy"
)
total_matrix <- comparison_matrix(matrices)
options(op)
```

---

compute_abundance           *Computes the abundance of every integration in the sample.*

---

### Description

[**Maturing**] Abundance is obtained for every row by calculating the ratio between the single value
and the total value for the sample.

### Usage

```
compute_abundance(x, columns = "Value", percentage = TRUE)
```

### Arguments

| | |
|---|---|
| x | An integration matrix - aka a data frame that includes the `mandatory_IS_vars()` as columns |
| columns | A character vector of column names to process, must be numeric or integer columns |
| percentage | Add abundance as percentage? |

### Details

Abundance will be computed upon the user selected columns in the `columns` parameter. For each
column a corresponding relative abundance column (and optionally a percentage abundance col-
umn) will be produced.

### Value

An integration matrix

### See Also

Other Analysis functions: CIS_grubbs(), comparison_matrix(), cumulative_count_union(),
sample_statistics(), separate_quant_matrices(), threshold_filter(), top_integrations()

### Examples

```
path <- system.file("extdata", "ex_annotated_ISMatrix.tsv.xz",
    package = "ISAnalytics"
)
matrix <- import_single_Vispa2Matrix(path)
abundance <- compute_abundance(matrix)
```

compute_near_integrations

*Scans input matrix to find and merge near integration sites.*

## Description

**[Experimental]** This function scans the input integration matrix to detect eventual integration sites that are too "near" to each other and merges them into single integration sites adjusting their values if needed.

## Usage

```
compute_near_integrations(
  x,
  threshold = 4,
  keep_criteria = "keep_first",
  strand_specific = TRUE,
  max_value_column = "seqCount",
  map_as_widget = TRUE,
  map_as_file = TRUE,
  file_path = ".",
  export_widget_path = NULL
)
```

## Arguments

| | |
|---|---|
| x | A single integration matrix, either with a single "Value" column or multiple value columns corresponding to different quantification types (obtained via [comparison_matrix](#)) |
| threshold | A single integer that represents an absolute number of bases for which two integrations are considered distinct |
| keep_criteria | While scanning, which integration should be kept? The 2 possible choices for this parameter are:<br>• "max_value": keep the integration site which has the highest value (and collapse other values on that integration).<br>• "keep_first": keeps the first integration |
| strand_specific | Should strand be considered? If yes, for example these two integration sites c(chr = "1", strand = "+", integration_locus = 14568) and c(chr = "1", strand = "-", integration_locus = 14568) are considered different and not grouped together. |
| max_value_column | The column that has to be considered for searching the maximum value |
| map_as_widget | Produce recalibration map as an HTML widget? |
| map_as_file | Produce recalibration map as a .tsv file? |
| file_path | String representing the path were the file will be saved. By default the function produces a folder in the current working directory and generates file names with time stamps. |
| export_widget_path | A path on disk to save produced widgets or NULL if the user doesn't wish to save the html file |

## Details

The whole matrix is scanned with a sliding window mechanism: for each row in the integration matrix an interval is calculated based on the threshold value, then a "look ahead" operation is performed to detect subsequent rows which integration locuses fall in the interval. If CompleteAmplificationIDs of the near integrations are different only the locus value (and optionally GeneName and GeneStrand if the matrix is annotated) is modified, otherwise rows with the same id are aggregated and values are summed. If one of the map parameters is set to true the function will also produce a re-calibration map: this data frame contains the reference of pre-recalibration values for chr, strand and integration locus and the value to which that integration was changed to after.

## Value

An integration matrix with same or less number of rows

## Note

We do recommend to use this function in combination with comparison_matrix to automatically perform re-calibration on all quantification matrices.

## Examples

```
path <- system.file("extdata", "ex_annotated_ISMatrix.tsv.xz",
    package = "ISAnalytics"
)
matrix <- import_single_Vispa2Matrix(path)
near <- compute_near_integrations(matrix,
    map_as_widget = FALSE,
    map_as_file = FALSE
)
```

---

cumulative_count_union

*Integrations cumulative count in time by sample*

---

## Description

**[Experimental]** This function computes the cumulative number of integrations observed in each sample at different time points by assuming that if an integration is observed at time point "t" then it is also observed in time point "t+1".

## Usage

```
cumulative_count_union(
  x,
  association_file = NULL,
  timepoint_column = "TimePoint",
  key = c("SubjectID", "CellMarker", "Tissue", "TimePoint"),
  include_tp_zero = FALSE,
  zero = "0000",
  aggregate = FALSE,
  ...
)
```

**Arguments**

| | |
|---|---|
| `x` | A simple integration matrix or an aggregated matrix (see details) |
| `association_file` | |
| | NULL or the association file for x if `aggregate` is set to TRUE |
| `timepoint_column` | |
| | What is the name of the time point column? |
| `key` | The aggregation key - must always contain the `timepoint_column` |
| `include_tp_zero` | |
| | Include timepoint 0? |
| `zero` | How is 0 coded in the data frame? |
| `aggregate` | Should x be aggregated? |
| `...` | Additional parameters to pass to `aggregate_values_by_key` |

**Details**

**Input data frame:**

The user can provide as input for the x parameter both a simple integration matrix AND setting the `aggregate` parameter to TRUE, or provide an already aggregated matrix via aggregate_values_by_key. If the user supplies a matrix to be aggregated the `association_file` parameter must not be NULL: aggregation will be done by an internal call to the aggregation function. If the user supplies an already aggregated matrix, the `key` parameter is the key used for aggregation - **NOTE: for this operation is mandatory that the time point column is included in the key.**

**Assumptions on time point format:**

By using the functions provided by this package, when imported, an association file will be correctly formatted for future usage. In the formatting process there is also a padding operation performed on time points: this means the functions expects the time point column to be of type character and to be correctly padded with 0s. If the chosen column for time point is detected as numeric the function will attempt the conversion to character and automatic padding. If you choose to import the association file not using the import_association_file function, be sure to check the format of the chosen column to avoid undesired results.

**Value**

A data frame

**See Also**

Other Analysis functions: CIS_grubbs(), comparison_matrix(), compute_abundance(), sample_statistics(), separate_quant_matrices(), threshold_filter(), top_integrations()

**Examples**

```
op <- options(ISAnalytics.widgets = FALSE)

path_AF <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_correct <- system.file("extdata", "fs.zip",
    package = "ISAnalytics"
)
root_correct <- unzip_file_system(root_correct, "fs")
```

```
association_file <- import_association_file(path_AF, root_correct,
    dates_format = "dmy"
)
matrices <- import_parallel_Vispa2Matrices_auto(
    association_file = association_file, root = NULL,
    quantification_type = c("seqCount", "fragmentEstimate"),
    matrix_type = "annotated", workers = 2, patterns = NULL,
    matching_opt = "ANY"
)

#### EXTERNAL AGGREGATION
aggregated <- aggregate_values_by_key(matrices$seqCount, association_file)
cumulative_count <- cumulative_count_union(aggregated)

#### INTERNAL AGGREGATION
cumulative_count_2 <- cumulative_count_union(matrices$seqCount,
    association_file,
    aggregate = TRUE
)

options(op)
```

---

date_columns_coll         *Possible choices for* date_col *parameter.*

---

### Description

Possible choices for date_col parameter.

### Usage

```
date_columns_coll()
```

### Value

A character vector of column names

### See Also

[remove_collisions](remove_collisions)

### Examples

```
dates <- date_columns_coll()
```

| date_formats | *Possible choices for the* dates_format *parameter in* import_association_file, import_parallel_vispa2Matrices_interactive *and* import_parallel_vispa2Matrices_auto. |
|---|---|

### Description

All options correspond to `lubridate` functions:

- ymd: year, month, date

- ydm: year, day, month

- mdy: month, day, year

- myd: month, year, day

- dmy: day, month, year - default value

- dym: day, year, month

- yq: year quantile

### Usage

```
date_formats()
```

### Details

**NOTE: use the same date format across the association file.**

### Value

A character vector

### See Also

[import_association_file](#), [import_parallel_Vispa2Matrices_auto](#)

### Examples

```
date_formats()
```

| default_stats | *A set of pre-defined functions for* sample_statistics. |
|---|---|

## Description

A set of pre-defined functions for sample_statistics.

## Usage

```
default_stats()
```

## Value

A named list of functions/purrr-style lambdas

## Examples

```
default_stats()
```

| generate_blank_association_file | |
|---|---|
| | *Creates a blank association file.* |

## Description

This function is useful if you want a blank association file to start using both Vispa2 and this package or simply if you want a correct framework to fix a malformed association file you have already.

## Usage

```
generate_blank_association_file(path)
```

## Arguments

path        The path on disk where the file should be written

## Value

returns NULL

## See Also

Other Utility functions: as_sparse_matrix(), generate_Vispa2_launch_AF(), unzip_file_system()

## Examples

```
temp <- tempfile()
generate_blank_association_file(temp)
```

generate_Vispa2_launch_AF

> *Creates a reduced association file for Vispa2 run, given project and pool*

### Description

The function selects the appropriate columns and prepares a file for the launch of Vispa2 pipeline for each project/pool pair specified.

### Usage

```
generate_Vispa2_launch_AF(association_file, project, pool, path)
```

### Arguments

association_file

> The imported association file (via `import_association_file`)

project             A vector of characters containing project names

pool                A vector of characters containing pool names. **NOTE: the names should refer to the values contained in the PoolID column of the association file and NOT the concatenatePoolIDSeqRun column!**

path                A single string representing the path to the folder where files should be written. If the folder doesn't exist it will be created.

### Details

Note: the function is vectorized, meaning you can specify more than one project and more than one pool as vectors of characters, but you must ensure that:

- Both `project` and `pool` vectors have the same length

- You correclty type names in corresponding positions, for example c("CLOEXP", "PROJECT1100", "PROJECT1100") - c("POOL6", "ABX-LR-PL5-POOL14-1", "ABX-LR-PL6-POOL15-1").
  If you type a pool in the position of a corresponding project that doesn't match no file will be produced since that pool doesn't exist in the corresponding project.

### Value

returns NULL

### See Also

Other Utility functions: [as_sparse_matrix](), [generate_blank_association_file](), [unzip_file_system]()

### Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
temp <- tempdir()
path_af <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
```

```
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
association_file <- import_association_file(path_af, root,
    dates_format = "dmy"
)
generate_Vispa2_launch_AF(association_file, "CLOEXP", "POOL6", temp)
options(op)
```

---

import_association_file

*Import the association file from disk*

---

## Description

[**Maturing**] Imports the association file and immediately performs a check on the file system starting from the root to assess the alignment between the two.

## Usage

```
import_association_file(
  path,
  root = NULL,
  tp_padding = 4,
  dates_format = "ymd",
  export_widget_path = NULL
)
```

## Arguments

| | |
|---|---|
| path | The path on disk to the association file. |
| root | The path on disk of the root folder of Vispa2 output or NULL. See details. |
| tp_padding | Timepoint padding, indicates the number of digits of the "Timepoint" column once imported. Fills the content with 0s up to the length specified (ex: 1 becomes 0001 with a tp_padding of 4) |
| dates_format | A single string indicating how dates should be parsed. Must be a value in: `date_formats()` |
| export_widget_path | A path on disk to save produced widgets or NULL if the user doesn't wish to save the html file |

## Details

The import series of functions is designed to work in combination with the use of Vispa2 pipeline, please refer to this article for more details: VISPA2: A Scalable Pipeline for High-Throughput Identification and Annotation of Vector Integration Sites.

The pipeline automatically produces an hierarchical structure in the file system which follows this schema:

- /root_folder
    - Optional intermediate folders

                              ∗ ProjectID
                                |_bam
                                |_bcmuxall
                                |_bed
                                |_iss
                                |_quality
                                |_report
                                |_quantification
                                *|___concatenatePoolIDSeqRun

For each ProjectID there may be several nested PoolIDs. The alignment function only looks for
PoolIDs in the quantification folder, since it's the location of the matrices to import. For more details
on how to properly use these functions, refer to the vignette - vignette("how_to_import_functions").
If 'NULL' the file system alignment step is skipped.

## Value

A tibble with the contents of the association file plus a column containing the path in the file system
for every project and pool if found.

## See Also

date_formats

Other Import functions: import_parallel_Vispa2Matrices_auto(), import_parallel_Vispa2Matrices_interact
import_single_Vispa2Matrix()

## Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
association_file <- import_association_file(path, root, dates_format = "dmy")
options(op)
```

---

import_parallel_Vispa2Matrices_auto

                    *Import integration matrices based on the association file.*

---

## Description

[**Maturing**] These functions are designed to import the appropriate integration matrix files given
the association file and the root folder of the file system where Vispa2 matrices are generated.

## Usage

```
import_parallel_Vispa2Matrices_auto(
  association_file,
  root,
  quantification_type,
  matrix_type = "annotated",
  workers = 2,
  patterns = NULL,
  matching_opt = matching_options(),
  tp_padding = 4,
  dates_format = "ymd",
  multi_quant_matrix = FALSE,
  export_widget_path = NULL,
  ...
)
```

## Arguments

association_file
: A single string containing the path to the association file on disk, or a tibble resulting from the previous call of `import_association_file`

root
: A single string containing the path to the root folder containing Vispa2 output. Can be NULL if association_file parameter is a tibble

quantification_type
: A vector of requested quantification_types. Must be one in `quantification_types()`

matrix_type
: A single string representing the type of matrices to be imported. Can only be one in `"annotated"` or `"not_annotated"`

workers
: A single number representing the number of parallel workers to use for the import

patterns
: A character vector of additional patterns to match on file names. Please note that patterns must be regular expressions. Can be NULL if no patterns needs to be matched.

matching_opt
: A single value between `matching_options`

tp_padding
: Timepoint padding, indicates the number of digits of the "Timepoint" column once imported. Fills the content with 0s up to the length specified (ex: 1 becomes 0001 with a tp_padding of 4)

dates_format
: A single string indicating how dates should be parsed. Must be a value in: `date_formats()`

multi_quant_matrix
: If set to TRUE will produce a multi-quantification matrix (data frame) through `comparison_matrix` instead of a list.

export_widget_path
: A path on disk to save produced widgets or NULL if the user doesn't wish to save the html file

...
: Additional arguments to pass to `comparison_matrix`

## Details

Import family functions are designed to work in combination with Vispa2, for more details on this take a look here: VISPA2: A Scalable Pipeline for High-Throughput Identification and Annotation

of Vector Integration Sites.
For more details on how to properly use these functions, refer to the vignette - vignette("how_to_import_functions")

**Value**

A named list of tibbles containing data from all imported integration matrices, divided by quantification type

**Automatic version**

The automatic version of import_parallel_Vispa2Matrices doesn't interact with the user directly, for this reason options in this modality are more limited compared to the interactive version. In automatic version you can't:

- Choose single projects or pools: to have a selection import the association file first and filter it according to your needs before calling the function (more details on this in the vignette)

- Choose duplicates: if, after filtering by the specified patterns, duplicates are found they are automatically ignored

**Interactive version**

The interactive version of import_parallel_Vispa2Matrices asks user for input and allows a more detailed choice of projects to import, pools to import and, if necessary, duplicate files. During the execution, a series of reports is shown in html format.

**See Also**

matching_options, https://stringr.tidyverse.org/articles/regular-expressions.html

Other Import functions: import_association_file(), import_parallel_Vispa2Matrices_interactive(), import_single_Vispa2Matrix()

**Examples**

```
op <- options("ISAnalytics.widgets" = FALSE)
path <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
matrices <- import_parallel_Vispa2Matrices_auto(
    path, root,
    c("fragmentEstimate", "seqCount"), "annotated", 2, NULL, "ANY",
    dates_format = "dmy"
)
options(op)
```

---

import_parallel_Vispa2Matrices_interactive
*Import integration matrices based on the association file.*

---

**Description**

[**Maturing**] These functions are designed to import the appropriate integration matrix files given the association file and the root folder of the file system where Vispa2 matrices are generated.

**Usage**

```
import_parallel_Vispa2Matrices_interactive(
  association_file,
  root,
  quantification_type,
  matrix_type = "annotated",
  workers = 2,
  tp_padding = 4,
  dates_format = "ymd",
  multi_quant_matrix = FALSE,
  export_widget_path = NULL,
  ...
)
```

**Arguments**

association_file

A single string containing the path to the association file on disk, or a tibble resulting from the previous call of `import_association_file`

root                    A single string containing the path to the root folder containing Vispa2 output. Can be NULL if association_file parameter is a tibble

quantification_type

A vector of requested quantification_types. Must be one in `quantification_types()`

matrix_type             A single string representing the type of matrices to be imported. Can only be one in "annotated" or "not_annotated"

workers                 A single number representing the number of parallel workers to use for the import

tp_padding              Timepoint padding, indicates the number of digits of the "Timepoint" column once imported. Fills the content with 0s up to the length specified (ex: 1 becomes 0001 with a tp_padding of 4)

dates_format            A single string indicating how dates should be parsed. Must be a value in: `date_formats()`

multi_quant_matrix

If set to TRUE will produce a multi-quantification matrix (data frame) through `comparison_matrix` instead of a list.

export_widget_path

A path on disk to save produced widgets or NULL if the user doesn't wish to save the html file

...                     Additional arguments to pass to `comparison_matrix`

## Details

## Examples

```
## Not run:
# Can't run because it's interactive and requires user input
matrices <- import_parallel_Vispa2Matrices_interactive(
    association_file,
    root, quantification_type, matrix_type, workers,
    dates_format = "dmy"
)

## End(Not run)
```

---

import_single_Vispa2Matrix

*Import a single integration matrix from file*

---

## Description

[Stable] This function allows to read and import an integration matrix produced as the output of Vispa2 pipeline and converts it to a tidy tibble.

## Usage

```
import_single_Vispa2Matrix(path)
```

## Arguments

path                The path to the file on disk

## Details

The import series of functions is designed to work in combination with the use of Vispa2 pipeline, please refer to this article for more details: VISPA2: A Scalable Pipeline for High-Throughput Identification and Annotation of Vector Integration Sites. For more details on how to properly use these functions, refer to vignette("How to use import functions", package = "ISAnalytics")

## Value

A tidy tibble

## See Also

Other Import functions: import_association_file(), import_parallel_Vispa2Matrices_auto(), import_parallel_Vispa2Matrices_interactive()

## Examples

```
path_to_file <- system.file("extdata", "ex_annotated_ISMatrix.tsv.xz",
    package = "ISAnalytics"
)
isa_dataframe <- import_single_Vispa2Matrix(path_to_file)
```

---

ISAnalytics                      *ISAnalytics: Analyze gene therapy vector insertion sites data identified from genomics next generation sequencing reads for clonal tracking studies*

---

## Description

[**Maturing**] In gene therapy, stem cells are modified using viral vectors to deliver the therapeutic transgene and replace functional properties since the genetic modification is stable and inherited in all cell progeny. The retrieval and mapping of the sequences flanking the virus-host DNA junctions allows the identification of insertion sites (IS), essential for monitoring the evolution of genetically modified cells in vivo. A comprehensive toolkit for the analysis of IS is required to foster clonal trackign studies and supporting the assessment of safety and long term efficacy in vivo. This package is aimed at (1) supporting automation of IS workflow, (2) performing base and advance analysis for IS tracking (clonal abundance, clonal expansions and statistics for insertional mutagenesis, etc.), (3) providing basic biology insights of transduced stem cells in vivo.

known_clinical_oncogenes

*Known clinical oncogenes (for mouse and human).*

---

## Description

Known clinical oncogenes (for mouse and human).

## Usage

```
known_clinical_oncogenes()
```

## Value

A data frame

**See Also**

Other Plotting function helpers: `clinical_relevant_suspicious_genes`()

**Examples**

```
known_clinical_oncogenes()
```

---

mandatory_IS_vars        *Names of mandatory variables for an integration matrix.*

---

**Description**

Contains the names of the columns that need to be present in order for a tibble to be considered an integration matrix.

**Usage**

```
mandatory_IS_vars()
```

**Value**

A character vector

**Examples**

```
mandatory_IS_vars()
```

---

matching_options        *Possible choices for the* matching_opt *parameter.*

---

**Description**

These are all the possible values for the matching_opt parameter in import_parallel_vispa2Matrices_auto.

**Usage**

```
matching_options()
```

**Details**

The values "ANY", "ALL" and "OPTIONAL", represent how the patterns should be matched, more specifically

- ANY = look only for files that match AT LEAST one of the patterns specified
- ALL = look only for files that match ALL of the patterns specified
- OPTIONAL = look preferentially for files that match, in order, all patterns or any pattern and if no match is found return what is found (keep in mind that duplicates are discarded in automatic mode)

## Value

A vector of characters for matching_opt

## See Also

[import_parallel_Vispa2Matrices_auto](#)

Other Import functions helpers: [quantification_types](#)()

## Examples

```
opts <- matching_options()
```

---

quantification_types       *Possible choices for the* quantification_type *parameter.*

---

## Description

These are all the possible values for the quantification_type parameter in import_parallel_vispa2Matrices_inte
and import_parallel_vispa2Matrices_auto.

## Usage

```
quantification_types()
```

## Details

The possible values are:

- fragmentEstimate
- seqCount
- barcodeCount
- cellCount
- ShsCount

## Value

A vector of characters for quantification types

## See Also

[import_parallel_Vispa2Matrices_interactive](#), [import_parallel_Vispa2Matrices_auto](#)

Other Import functions helpers: [matching_options](#)()

## Examples

```
quant_types <- quantification_types()
```

```
realign_after_collisions
```
*Re-aligns matrices of other quantification types based on the processed sequence count matrix.*

## Description

**[Experimental]** This function should be used to keep data consistent among the same analysis: if for some reason you removed the collisions by passing only the sequence count matrix to the `remove_collisions` function, you should call this function afterwards, providing a list of other quantification matrices. NOTE: if you provided a list of several quantification types to `remove_collisions` before, there is no need to call this function.

## Usage

```
realign_after_collisions(sc_matrix, other_matrices)
```

## Arguments

sc_matrix       The sequence count matrix already processed for collisions via `remove_collisions`

other_matrices  A named list of matrices to re-align. Names in the list must be quantification types (`quantification_types()`) except "seqCount".

## Details

For more details on how to use collision removal functionality: `vignette("Collision removal functionality", package = "ISAnalytics")`

## Value

A named list with re-aligned matrices

## See Also

[remove_collisions](#)

Other Collision removal: [remove_collisions](#)()

## Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
association_file <- import_association_file(path, root,
    dates_format = "dmy"
)
matrices <- import_parallel_Vispa2Matrices_auto(
    association_file, NULL,
    c("fragmentEstimate", "seqCount"), "annotated", 2, NULL, "ANY"
)
```

```
sc_matrix <- remove_collisions(matrices$seqCount, association_file)
others <- matrices[!names(matrices) %in% "seqCount"]
aligned_matrices <- realign_after_collisions(sc_matrix, others)
options(op)
```

---

| reduced_AF_columns | *Names of the columns of the association file to consider for Vispa2 launch.* |
|---|---|

---

## Description

Selection of column names from the association file to be considered for Vispa2 launch. NOTE: the `TagID` column appears only once but needs to be repeated twice for generating the launch file. Use the appropriate function to generate the file automatically.

## Usage

```
reduced_AF_columns()
```

## Value

A character vector

## Examples

```
reduced_AF_columns()
```

---

| remove_collisions | *Identifies and removes collisions based on the sequence count matrix.* |
|---|---|

---

## Description

**[Experimental]** A collision is an integration (aka a unique combination of chr, integration_locus and strand) which is observed in more than one independent sample (a unique pair of ProjectID and SubjectID). The function tries to decide to which subject an integration should be assigned and if no decision can be taken, the integration is completely removed from the data frame.

## Usage

```
remove_collisions(
  x,
  association_file,
  date_col = "SequencingDate",
  reads_ratio = 10,
  seq_count_col = "seqCount",
  max_rows_reports = 50,
  save_widget_path = NULL
)
```

## Arguments

| | |
|---|---|
| x | A named list of matrices (names must be quantification types), a single integration matrix representing the sequence count matrix of interest or a multi-quantification matrix obtained via comparison_matrix |
| association_file | |
| | The association file imported via import_association_file |
| date_col | The date column that should be considered for the analysis. Must be one value in date_columns_coll() |
| reads_ratio | A single numeric value that represents the ratio that has to be considered when deciding between seqCount value. |
| seq_count_col | For support of multi-quantification matrix - the name of the sequence count values column |
| max_rows_reports | |
| | A numeric value, represents the maximum number of rows of the reports data frames that can be printed on console if the option ISAnalytics.verbose is active. If the data frames are too large they won't be printed on console - we recommend using widgets for detailed and more accessible info. |
| save_widget_path | |
| | Either NULL or a path where the html report file should be saved. If NULL the report is visualized via browser ONLY (not saved on disk). |

## Details

If you don't want the function to show details and messages do: options(ISAnalitics.verbose = FALSE). To restore to the original value: options(ISAnalitics.verbose = TRUE). For more details on how to use collision removal functionality: vignette("Collision removal functionality",package = "ISAnalytics")

## Value

A list of tibbles with removed collisions

## See Also

date_columns_coll

Other Collision removal: realign_after_collisions()

## Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
association_file <- import_association_file(path, root,
    dates_format = "dmy"
)
matrices <- import_parallel_Vispa2Matrices_auto(
    association_file, NULL,
    c("fragmentEstimate", "seqCount"), "annotated", 2, NULL, "ANY"
)
```

```
matrices <- remove_collisions(matrices, association_file)
options(op)
```

---

sample_statistics          *Computes user specified functions on numerical columns and updates*
                           *the metadata data frame accordingly.*

---

## Description

**[Experimental]** The function operates on a data frame by grouping the content by the sample
key and computing every function specified on every column in the `value_columns` parameter.
After that the metadata data frame is updated by including the computed results as columns for the
corresponding key. For this reason it's required that both `x` and `metadata` have the same sample key,
and it's particularly important if the user is working with previously aggregated data. For example:

```
### Importing association file and matrices
path_AF <- system.file("extdata", "ex_association_file.tsv",
package = "ISAnalytics")
root_correct <- system.file("extdata", "fs.zip",
package = "ISAnalytics")
root_correct <- unzip_file_system(root_correct, "fs")

association_file <- import_association_file(path_AF, root_correct)
matrices <- import_parallel_Vispa2Matrices_auto(
association_file = association_file , root = NULL,
quantification_type = c("seqCount","fragmentEstimate"),
matrix_type = "annotated", workers = 2, patterns = NULL,
matching_opt = "ANY", dates_format = "dmy")

### Aggregating data (both by same key)
aggreggated_x <- aggregate_values_by_key(matrices$seqCount,
association_file)
aggregated_meta <- aggregate_metadata(association_file)

### Sample statistics
sample_stats <- sample_statistics(x = aggregated_x,
metadata = aggregated_meta,
sample_key = c("SubjectID", "CellMarker","Tissue", "TimePoint"))
```

## Usage

```
sample_statistics(
  x,
  metadata,
  sample_key = "CompleteAmplificationID",
  value_columns = "Value",
  functions = default_stats()
)
```

## Arguments

| | |
|---|---|
| `x` | A data frame |
| `metadata` | The metadata data frame |
| `sample_key` | Character vector representing the key for identifying a sample |
| `value_columns` | THe name of the columns to be computed, must be numeric or integer |
| `functions` | A named list of function or purrr-style lambdas |

## Value

A list with modified x and metadata data frames

## See Also

Other Analysis functions: [CIS_grubbs()](), [comparison_matrix()](), [compute_abundance()](), [cumulative_count_union]()
[separate_quant_matrices](), [threshold_filter](), [top_integrations]()

## Examples

```
op <- options(ISAnalytics.widgets = FALSE)

path_AF <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_correct <- system.file("extdata", "fs.zip",
    package = "ISAnalytics"
)
root_correct <- unzip_file_system(root_correct, "fs")

association_file <- import_association_file(path_AF, root_correct,
    dates_format = "dmy"
)

separate_quant_matrices

*Separate a multiple-quantification matrix into single quantification matrices.*

---

## Description

**[Maturing]** The function separates a single multi-quantification integration matrix, obtained via
[comparison_matrix](), into single quantification matrices as a named list of tibbles.

## Usage

```
separate_quant_matrices(
  x,
  fragmentEstimate = "fragmentEstimate",
  seqCount = "seqCount",
  barcodeCount = "barcodeCount",
  cellCount = "cellCount",
  ShsCount = "ShsCount"
)
```

## Arguments

| | |
|---|---|
| x | Single integration matrix with multiple quantification value columns, likely obtained via comparison_matrix. |
| fragmentEstimate | |
| | Name of the fragment estimate values column in input |
| seqCount | Name of the sequence count values column in input |
| barcodeCount | Name of the barcode count values column in input |
| cellCount | Name of the cell count values column in input |
| ShsCount | Name of the shs count values column in input |

## Value

A named list of tibbles, where names are quantification types

## See Also

quantification_types

Other Analysis functions: CIS_grubbs(), comparison_matrix(), compute_abundance(), cumulative_count_union
sample_statistics(), threshold_filter(), top_integrations()

## Examples

```
op <- options("ISAnalytics.widgets" = FALSE)
path <- system.file("extdata", "ex_association_file.tsv",
    package = "ISAnalytics"
)
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
matrices <- import_parallel_Vispa2Matrices_auto(
    path, root,
    c("fragmentEstimate", "seqCount"), "annotated", 2, NULL, "ANY",
    dates_format = "dmy"
)
total_matrix <- comparison_matrix(matrices)
separated_matrix <- separate_quant_matrices(total_matrix)
options(op)
```

threshold_filter          *Filter data frames with custom predicates*

---

**Description**

[Experimental] Filter a single data frame or a list of data frames with custom predicates assembled from the function parameters.

**Usage**

```
threshold_filter(x, threshold, cols_to_compare = "Value", comparators = ">")
```

**Arguments**

| | |
|---|---|
| x | A data frame or a list of data frames |
| threshold | A numeric/integer vector or a named list of numeric/integer vectors |
| cols_to_compare | |
| | A character vector or a named list of character vectors |
| comparators | A character vector or a named list of character vectors. Must be one of the allowed values between c("<",">","==","!=",">=","<=") |

**Details**

**A single data frame as input:**

If the user chooses to operate on a single data frame, the other parameters should only be vectors: numeric vector for threshold and character vectors for both cols_to_compare and comparators. A filtering condition is obtained by combining element by element cols_to_compare + comparators + threshold (similarly to the paste function). For example:

threshold = c(20, 35, 50)

cols_to_compare = c("a", "b", "c")

comparators = "<"

given these vectors, the input data frame will be filtered by checking which values in column "a" are less than 20 **AND** which values in column "b" are less than 35 **AND** which values in column "c" are less than 50. Things the user should keep in mind are:

- The vectors of length 1 are going to be recycled if one or more parameters are longer (in the example, the comparators value)
- If vectors are not of length 1 they must have the same length
- Columns to compare, of course, need to be included in the input data frame and need to be numeric/integer
- The filtering will perform a logical "AND" on all the conditions, only rows that satisfy ALL the conditions are preserved

**A list of data frames as input:**

The input for the function may also be a list of data frames, either named or unnamed.

*Unnamed list:*

If the input is a simple unnamed list, the other parameters should be simple vectors (as for data frames). All the predicates will simply be applied to every data frame in the list: this is useful if it's desirable to filter for the same conditions different data frames that have the same structure but different data.

*Named list:*
It is also possible to filter different data frames with different sets of conditions. Besides having
the possibility of defining the other parameters as simple vector, which has the same results
as operating on an unnamed list, the user can define the parameters as named lists containing
vectors. For example:

```
example_df <- tibble::tibble(a = c(20, 30, 40),
                             b = c(40, 50, 60),
                             c = c("a", "b", "c"),
                             d = c(3L, 4L, 5L))
example_list <- list(first = example_df,
                     second = example_df,
                     third = example_df)
print(example_list)
## $first
## # A tibble: 3 x 4
##       a     b c         d
##   <dbl> <dbl> <chr> <int>
## 1    20    40 a         3
## 2    30    50 b         4
## 3    40    60 c         5
##
## $second
## # A tibble: 3 x 4
##       a     b c         d
##   <dbl> <dbl> <chr> <int>
## 1    20    40 a         3
## 2    30    50 b         4
## 3    40    60 c         5
##
## $third
## # A tibble: 3 x 4
##       a     b c         d
##   <dbl> <dbl> <chr> <int>
## 1    20    40 a         3
## 2    30    50 b         4
## 3    40    60 c         5
filtered <- threshold_filter(example_list,
                             threshold = list(first = c(20, 60),
                                              third = c(25)),
                             cols_to_compare = list(first = c("a", "b"),
                                                    third = c("a")),
                             comparators = list(first = c(">", "<"),
                                                third = c(">=")))
print(filtered)
## $first
## # A tibble: 1 x 4
##       a     b c         d
##   <dbl> <dbl> <chr> <int>
## 1    30    50 b         4
##
## $second
## # A tibble: 3 x 4
```

```
##        a     b c        d
##    <dbl> <dbl> <chr> <int>
## 1    20    40 a        3
## 2    30    50 b        4
## 3    40    60 c        5
##
## $third
## # A tibble: 2 x 4
##        a     b c        d
##    <dbl> <dbl> <chr> <int>
## 1    30    50 b        4
## 2    40    60 c        5
```

The above signature will roughly be translated as:

- Filter the element "first" in the list by checking that values in column "a" are bigger than 20 AND values in column "b" are less than 60
- Don't apply any filter to the element "second" (returns the data frame as is)
- Filter the element "third" by checking that values in column "a" are equal or bigger than 25.

It is also possible to use some parameters as vectors and some as lists: vectors will be recycled for every element filtered.

```
filtered <- threshold_filter(example_list,
                             threshold = list(first = c(20, 60),
                                              third = c(25, 65)),
                             cols_to_compare = c("a", "b"),
                             comparators = list(first = c(">", "<"),
                                                third = c(">=", "<="))))
```

In this example, different threshold and comparators will be applied to the same columns in all data frames.

Things the user should keep in mind are:

- Names for the list parameters must be the same names in the input list
- Only elements explicited in list parameters as names will be filtered
- Lengths of both vectors and lists must be consistent

### Value

A data frame or a list of data frames

### See Also

Other Analysis functions: `CIS_grubbs()`, `comparison_matrix()`, `compute_abundance()`, `cumulative_count_union` `sample_statistics()`, `separate_quant_matrices()`, `top_integrations()`

### Examples

```
example_df <- tibble::tibble(
    a = c(20, 30, 40),
    b = c(40, 50, 60),
    c = c("a", "b", "c"),
    d = c(3L, 4L, 5L)
)
example_list <- list(
    first = example_df,
    second = example_df,
```

```
        third = example_df
    )
)

filtered <- threshold_filter(example_list,
    threshold = list(
        first = c(20, 60),
        third = c(25)
    ),
    cols_to_compare = list(
        first = c("a", "b"),
        third = c("a")
    ),
    comparators = list(
        first = c(">", "<"),
        third = c(">=")
    )
)
```

---

top_integrations                    *Sorts and keeps the top n integration sites in a data frame.*

---

### Description

[Experimental] The input data frame will be sorted by the highest values in the columns specified and the top n rows will be returned as output. The user can choose to keep additional columns in the output by passing a vector of column names or passing 2 "shortcuts":

- keep = "everything" keeps all columns in the original data frame
- keep = "nothing" only keeps the mandatory columns (mandatory_IS_vars()) plus the columns in the columns parameter.

### Usage

```
top_integrations(x, n = 50, columns = "RelAbundance", keep = "everything")
```

### Arguments

| | |
|---|---|
| x | An integration matrix (data frame containing mandatory_IS_vars()) |
| n | How many rows should the output have? Must be numeric or integer and greater than 0 |
| columns | Columns to use for the sorting. If more than a column is supplied primary ordering is done on the first column, secondary ordering on all other columns |
| keep | Names of the columns to keep besides mandatory_IS_vars() and columns |

### Value

A data frame with n rows

### See Also

Other Analysis functions: CIS_grubbs(), comparison_matrix(), compute_abundance(), cumulative_count_union sample_statistics(), separate_quant_matrices(), threshold_filter()

## Examples

```
smpl <- tibble::tibble(
    chr = c("1", "2", "3", "4", "5", "6"),
    integration_locus = c(14536, 14544, 14512, 14236, 14522, 14566),
    strand = c("+", "+", "-", "+", "-", "+"),
    CompleteAmplificationID = c("ID1", "ID2", "ID1", "ID1", "ID3", "ID2"),
    Value = c(3, 10, 40, 2, 15, 150),
    Value2 = c(456, 87, 87, 9, 64, 96),
    Value3 = c("a", "b", "c", "d", "e", "f")
)
top <- top_integrations(smpl,
    n = 3,
    columns = c("Value", "Value2"),
    keep = "nothing"
)
```

---

unzip_file_system          *A utility function to unzip and use example file systems included in the package*

---

### Description

This utility function is a simple shortcut to create a temporary directory, unzip and reference the examples file systems included in the package for testing purposes.

### Usage

```
unzip_file_system(zipfile, name)
```

### Arguments

| | |
|---|---|
| zipfile | The zipped file to decompress |
| name | The name of the folder in the zipped archive ("fs" or "fserr") |

### Value

A path to reference

### See Also

Other Utility functions: as_sparse_matrix(), generate_Vispa2_launch_AF(), generate_blank_association_fil

### Examples

```
root_pth <- system.file("extdata", "fs.zip", package = "ISAnalytics")
root <- unzip_file_system(root_pth, "fs")
```
