

Package ‘GenomeInfoDb’

October 18, 2022

Title Utilities for manipulating chromosome names, including modifying them to follow a particular naming style

Description Contains data and functions that define and allow translation between different chromosome sequence naming conventions (e.g., ‘chr1’ versus ‘1’), including a function that attempts to place sequence names in their natural, rather than lexicographic, order.

GenomeDescription-class
GenomeDescription objects

Description

A GenomeDescription object holds the meta information describing a given genome.

Constructor

Even though a constructor function is provided (`GenomeDescription()`), it is rarely needed. GenomeDescription objects are typically obtained by coercing a [BSgenome](#) object to GenomeDescription. This has the effect of stripping the sequences from the object and retaining only the meta information that describes the genome. See the Examples section below for an example.

Accessor methods

In the code snippets below, `object` or `x` is a GenomeDescription object.

`organism(object)`: Return the scientific name of the organism of the genome e.g. "Homo sapiens", "Mus musculus", "Caenorhabditis elegans", etc...

`commonName(object)`: Return the common name of the organism of the genome e.g. "Human", "Mouse", "Worm", etc...

`providerVersion(x)`: Return the *name* of the genome. This is typically the name of an NCBI assembly (e.g. GRCh38.p13, WBcel1235, TAIR10.1, ARS-UCD1.2, etc...) or UCSC genome (e.g. hg38, bosTau9, galGal6, ce11, etc...).

`provider(x)`: Return the provider of this genome e.g. "UCSC", "BDGP", "FlyBase", etc...

`releaseDate(x)`: Return the release date of this genome e.g. "Mar. 2006".

`releaseName(x)`: IMPORTANT NOTE: After being deprecated in Bioconductor 3.12, the `releaseName()` methods for `GenomeDescription` and `BSgenome` objects are defunct in Bioconductor 3.15!

If `x` is a `GenomeDescription` object, `releaseName(x)` returns the release name of this genome, which is usually made of the name of the organization who assembled it plus its Build version. For example, UCSC uses "hg18" for the version of the Human genome corresponding to the Build 36.1 from NCBI hence the release name for this genome is "NCBI Build 36.1".

If `x` is a `BSgenome` object, `releaseName(x)` returns `NA_character_`.

`bsgenomeName(x)`: Uses the meta information stored in `GenomeDescription` object `x` to construct the name of the corresponding `BSgenome` data package (see the [available.genomes](#) function in the **BSgenome** package for details about the naming scheme used for those packages). Note that there is no guarantee that a package with that name actually exists.

`seqinfo(x)` Gets information about the genome sequences. This information is returned in a `Seqinfo` object. Each part of the information can be retrieved separately with `seqnames(x)`, `seqlengths(x)`, and `isCircular(x)`, respectively, as described below.

`seqnames(x)` Gets the names of the genome sequences. `seqnames(x)` is equivalent to `seqnames(seqinfo(x))`.

`seqlengths(x)` Gets the lengths of the genome sequences. `seqlengths(x)` is equivalent to `seqlengths(seqinfo(x))`.

`isCircular(x)` Returns the circularity flags of the genome sequences. `isCircular(x)` is equivalent to `isCircular(seqinfo(x))`.

- The `Seqinfo` class.

Examples

```
library(BSgenome.Celegans.UCSC.ce2)
BSgenome.Celegans.UCSC.ce2
as(BSgenome.Celegans.UCSC.ce2, "GenomeDescription")
```

```
getChromInfoFromEnsembl
```

Get chromosome information for an Ensembl species

Description

getChromInfoFromEnsembl returns chromosome information like sequence names, lengths and circularity flags for a given Ensembl species e.g. Human, Cow, Saccharomyces cerevisiae, etc...

Usage

```
getChromInfoFromEnsembl(species,
                          release=NA, division=NA, use.grch37=FALSE,
                          assembled.molecules.only=FALSE,
                          include.non_ref.sequences=FALSE,
                          include.contigs=FALSE,
                          include.clones=FALSE,
                          map.NCBI=FALSE,
                          recache=FALSE,
                          as.Seqinfo=FALSE)
```

Arguments

species	A single string specifying the name of an Ensembl species e.g. "human", "hsapiens", or "Homo sapiens". Case is ignored. Alternatively the name of an assembly (e.g. "GRCh38") or a taxonomy id (e.g. 9606) can be supplied.
release	The Ensembl release to query e.g. 89. If set to NA (the default), the current release is used.
division	NA (the default) or one of the EnsemblGenomes marts i.e. "bacteria", "fungi", "metazoa", "plants", or "protists".
use.grch37	NOT TESTED YET! TRUE or FALSE (the default).
assembled.molecules.only	NOT IMPLEMENTED YET!
include.non_ref.sequences	TODO: DOCUMENT THIS!
include.contigs	Whether or not sequences for which coord_system is set to "contig" should be included. They are not included by default. Note that the dataset for Human contains more than one hundred thousands <i>contigs</i> !
include.clones	Whether or not sequences for which coord_system is set to "clone" should be included. They are not included by default. Note that the dataset for Human contains more than one hundred thousands <i>clones</i> !

map.NCBI	<p>TRUE or FALSE (the default).</p> <p>If TRUE then NCBI chromosome information is bound to the result. This information is retrieved from NCBI by calling <code>getChromInfoFromNCBI</code> on the NCBI assembly that the Ensembl species is based on. Then the data frame returned by <code>getChromInfoFromNCBI</code> ("NCBI chrom info") is <i>mapped</i> and bound to the data frame returned by <code>getChromInfoFromEnsembl</code> ("Ensembl chrom info"). This "map and bind" operation is similar to a JOIN in SQL.</p> <p>Note that not all rows in the "Ensembl chrom info" data frame are necessarily mapped to a row in the "NCBI chrom info" data frame. For the unmapped rows the NCBI columns in the final data frame are filled with NAs (LEFT JOIN in SQL).</p> <p>The primary use case for using <code>map.NCBI=TRUE</code> is to map Ensembl sequence names to NCBI sequence names.</p>
recache	<p><code>getChromInfoFromEnsembl</code> uses a cache mechanism so the chromosome information of a given dataset only gets downloaded once during the current R session (note that the caching is done in memory so cached information does NOT persist across sessions). Setting <code>recache</code> to TRUE forces a new download (and recaching) of the chromosome information for the specified dataset.</p>
as.Seqinfo	<p>TRUE or FALSE (the default). If TRUE then a <code>Seqinfo</code> object is returned instead of a data frame. Note that only the name, length, and circular columns of the data frame are used to make the <code>Seqinfo</code> object. All the other columns are ignored (and lost).</p>

Details

COMING SOON...

Value

For `getChromInfoFromEnsembl`: By default, a 7-column data frame with columns:

1. name: character.
2. length: integer.
3. coord_system: factor.
4. synonyms: list.
5. toplevel: logical.
6. non_ref: logical.
7. circular: logical.

and with attribute `species_info` which contains details about the species that was used to obtain the data.

If `map.NCBI` is TRUE, then 7 "NCBI columns" are added to the result:

- `NCBI.SequenceName`: character.
- `NCBI.SequenceRole`: factor.
- `NCBI.AssignedMolecule`: factor.

- `NCBI.GenBankAccn`: character.
- `NCBI.Relationship`: factor.
- `NCBI.RefSeqAccn`: character.
- `NCBI.AssemblyUnit`: factor.

Note that the names of the "NCBI columns" are those returned by `getChromInfoFromNCBI` but with the `NCBI.` prefix added to them.

## End(Not run)
```

```
getChromInfoFromNCBI  Get chromosome information for an NCBI assembly
```

Description

getChromInfoFromNCBI returns chromosome information like sequence names, lengths and circularity flags for a given NCBI assembly e.g. for GRCh38, ARS-UCD1.2, R64, etc...

Note that getChromInfoFromNCBI behaves slightly differently depending on whether the assembly is *registered* in the **GenomeInfoDb** package or not. See below for the details.

Use registered_NCBI_assemblies to list all the NCBI assemblies currently registered in the **GenomeInfoDb** package.

Usage

```
getChromInfoFromNCBI(assembly,
                     assembled.molecules.only=FALSE,
                     assembly.units=NULL,
                     recache=FALSE,
                     as.Seqinfo=FALSE)
```

```
registered_NCBI_assemblies(organism=NA)
```

Arguments

assembly	A single string specifying the name of an NCBI assembly (e.g. "GRCh38"). Alternatively, an assembly accession (GenBank or RefSeq) can be supplied (e.g. "GCF_000001405.12").
assembled.molecules.only	If FALSE (the default) then chromosome information is returned for all the sequences in the assembly (unless assembly.units is specified, see below), that is, for all the chromosomes, plasmids, and scaffolds. If TRUE then chromosome information is returned only for the <i>assembled molecules</i> . These are the chromosomes (including the mitochondrial chromosome) and plasmids only. No scaffolds.
assembly.units	If NULL (the default) then chromosome information is returned for all the sequences in the assembly (unless assembled.molecules.only is set to TRUE, see above), that is, for all the chromosomes, plasmids, and scaffolds. assembly.units can be set to a character vector containing the names of <i>Assembly Units</i> (e.g. "non-nuclear") in which case chromosome information is returned only for the sequences that belong to these Assembly Units.

recache	getChromInfoFromNCBI uses a cache mechanism so the chromosome information of a given assembly only gets downloaded once during the current R session (note that the caching is done in memory so cached information does NOT persist across sessions). Setting recache to TRUE forces a new download (and recaching) of the chromosome information for the specified assembly.
as.Seqinfo	TRUE or FALSE (the default). If TRUE then a Seqinfo object is returned instead of a data frame. Note that only the SequenceName, SequenceLength, and circular columns of the data frame are used to make the Seqinfo object. All the other columns are ignored (and lost).
organism	When organism is specified, registered_NCBI_assemblies() will only return the subset of assemblies that are registered for that organism. organism must be specified as a single string and will be used to perform a search (with grep()) on the "organism" column of the data frame returned by registered_NCBI_assemblies(). The search is case-insensitive.

Details

registered vs unregistered NCBI assemblies:

- All NCBI assemblies can be looked up by assembly accession (GenBank or RefSeq) but only *registered* assemblies can also be looked up by assembly name.
- For *registered* assemblies, the returned circularity flags are guaranteed to be accurate. For *unregistered* assemblies, a heuristic is used to determine the circular sequences.

Please contact the maintainer of the **GenomeInfoDb** package to request registration of additional assemblies.

Value

For getChromInfoFromNCBI: By default, a 10-column data frame with columns:

1. SequenceName: character.
2. SequenceRole: factor.
3. AssignedMolecule: factor.
4. GenBankAccn: character.
5. Relationship: factor.
6. RefSeqAccn: character.
7. AssemblyUnit: factor.
8. SequenceLength: integer. Note that this column **can** contain NAs! For example this is the case in assembly Amel_HAv3.1 where the length of sequence MT is missing or in assembly Release 5 where the length of sequence Un is missing.
9. UCSCStyleName: character.
10. circular: logical.

For registered_NCBI_assemblies: A data frame summarizing all the NCBI assemblies currently *registered* in the **GenomeInfoDb** package.

Examples

```
## All registered NCBI assemblies for Triticum aestivum (bread wheat):
registered_NCBI_assemblies("tri")[1:4]

## All registered NCBI assemblies for Homo sapiens:
registered_NCBI_assemblies("homo")[1:4]

## Internet access required!
getChromInfoFromNCBI("GRCh37")
getChromInfoFromNCBI("GRCh37", as.Seqinfo=TRUE)
getChromInfoFromNCBI("GRCh37", assembled.molecules.only=TRUE)

## The GRCh38.p14 assembly only adds "patch sequences" to the GRCh38
## assembly:
GRCh38 <- getChromInfoFromNCBI("GRCh38")
table(GRCh38$SequenceRole)
GRCh38.p14 <- getChromInfoFromNCBI("GRCh38.p14")
table(GRCh38.p14$SequenceRole) # 254 patch sequences (164 fix + 90 novel)

## All registered NCBI assemblies for Arabidopsis thaliana:
registered_NCBI_assemblies("arabi")[1:4]
getChromInfoFromNCBI("TAIR10.1")
getChromInfoFromNCBI("TAIR10.1", assembly.units="non-nuclear")

## Sanity checks:
idx <- match(GRCh38$SequenceName, GRCh38.p14$SequenceName)
stopifnot(!anyNA(idx))
tmp1 <- GRCh38.p14[idx, ]
rownames(tmp1) <- NULL
tmp2 <- GRCh38.p14[-idx, ]
stopifnot(
  identical(tmp1[ , -(5:7)], GRCh38[ , -(5:7)]),
  identical(tmp2, GRCh38.p14[GRCh38.p14$AssemblyUnit == "PATCHES", ])
)
```

Description

getChromInfoFromUCSC returns chromosome information like sequence names, lengths and circularity flags for a given UCSC genome e.g. for hg19, panTro6, sacCer3, etc...

Note that getChromInfoFromUCSC behaves slightly differently depending on whether a genome is *registered* in the **GenomeInfoDb** package or not. See below for the details.

Use registered_UCSC_genomes to list all the UCSC genomes currently registered in the **GenomeInfoDb** package.

Usage

```
getChromInfoFromUCSC(genome,
                      assembled.molecules.only=FALSE,
                      map.NCBI=FALSE,
                      add.ensembl.col=FALSE,
                      goldenPath.url=getOption("UCSC.goldenPath.url"),
                      recache=FALSE,
                      as.Seqinfo=FALSE)
```

```
registered_UCSC_genomes()
```

Arguments

genome	A single string specifying the name of a UCSC genome (e.g. "panTro6").
assembled.molecules.only	<p>If FALSE (the default) then chromosome information is returned for all the sequences in the genome, that is, for all the chromosomes, plasmids, and scaffolds.</p> <p>If TRUE then chromosome information is returned only for the <i>assembled molecules</i>. These are the chromosomes (including the mitochondrial chromosome) and plasmids only. No scaffolds.</p> <p>Note that assembled.molecules.only=TRUE is supported only for <i>registered</i> genomes. When used on an <i>unregistered</i> genome, assembled.molecules.only is ignored with a warning.</p>
map.NCBI	<p>TRUE or FALSE (the default).</p> <p>If TRUE then NCBI chromosome information is bound to the result. This information is retrieved from NCBI by calling <code>getChromInfoFromNCBI</code> on the NCBI assembly that the UCSC genome is based on. Then the data frame returned by <code>getChromInfoFromNCBI</code> ("NCBI chrom info") is <i>mapped</i> and bound to the data frame returned by <code>getChromInfoFromUCSC</code> ("UCSC chrom info"). This "map and bind" operation is similar to a JOIN in SQL.</p> <p>Note that not all rows in the "UCSC chrom info" data frame are necessarily mapped to a row in the "NCBI chrom info" data frame. For example chrM in hg19 has no corresponding sequence in the GRCh37 assembly (the mitochondrial chromosome was omitted from GRCh37). For the unmapped rows the NCBI columns in the final data frame are filled with NAs (LEFT JOIN in SQL).</p> <p>The primary use case for using map.NCBI=TRUE is to map UCSC sequence names to NCBI sequence names. This is only supported for <i>registered</i> UCSC genomes based on an NCBI assembly!</p>

<code>add.ensembl.col</code>	TRUE or FALSE (the default). Whether or not the Ensembl sequence names should be added to the result (in column <code>ensembl</code>).
<code>goldenPath.url</code>	A single string specifying the URL to the UCSC <code>goldenPath</code> location where the chromosome sizes are expected to be found.
<code>recache</code>	<code>getChromInfoFromUCSC</code> uses a cache mechanism so the chromosome sizes of a given genome only get downloaded once during the current R session (note that the caching is done in memory so cached information does NOT persist across sessions). Setting <code>recache</code> to TRUE forces a new download (and recaching) of the chromosome sizes for the specified genome.
<code>as.Seqinfo</code>	TRUE or FALSE (the default). If TRUE then a <code>Seqinfo</code> object is returned instead of a data frame. Note that only the <code>chrom</code> , <code>size</code> , and <code>circular</code> columns of the data frame are used to make the <code>Seqinfo</code> object. All the other columns are ignored (and lost).

Details

registered vs unregistered UCSC genomes:

- `assembled.molecules.only=TRUE` is supported only for *registered* genomes. For *unregistered* genomes, the argument is ignored with a warning.
- For *registered* genomes, the returned circularity flags are guaranteed to be accurate. For *unregistered* genomes, a heuristic is used to determine the circular sequences.
- For *registered* genomes, special care is taken to make sure that the sequences are returned in a sensible order. For *unregistered* genomes, a heuristic is used to return the sequence in a sensible order.

Please contact the maintainer of the **GenomeInfoDb** package to request registration of additional genomes.

Value

For `getChromInfoFromUCSC`: By default, a 4-column data frame with columns:

1. `chrom`: character.
2. `size`: integer.
3. `assembled`: logical.
4. `circular`: logical.

If `map.NCBI` is TRUE, then 7 "NCBI columns" are added to the result:

- `NCBI.SequenceName`: character.
- `NCBI.SequenceRole`: factor.
- `NCBI.AssignedMolecule`: factor.
- `NCBI.GenBankAccn`: character.
- `NCBI.Relationship`: factor.
- `NCBI.RefSeqAccn`: character.

- `NCBI.AssemblyUnit`: factor.

Note that the names of the "NCBI columns" are those returned by `getChromInfoFromNCBI` but with the `NCBI.` prefix added to them.

If `add.ensembl.col` is `TRUE`, the column `ensembl` is added to the result.

For `registered_UCSC_genomes`: A data frame summarizing all the UCSC genomes currently *registered* in the **GenomeInfoDb** package.

Examples

```
## -----
## A. BASIC EXAMPLES
## -----

## Internet access required!

getChromInfoFromUCSC("hg19")

getChromInfoFromUCSC("hg19", as.Seqinfo=TRUE)

getChromInfoFromUCSC("hg19", assembled.molecules.only=TRUE)

getChromInfoFromUCSC("panTro6", assembled.molecules.only=TRUE)

## Map the hg38 sequences to their corresponding sequences in
## the GRCh38.p13 assembly:
getChromInfoFromUCSC("hg38", map.NCBI=TRUE)[c(1, 5)]

## Note that some NCBI-based UCSC assemblies contain sequences that
## are not mapped. For example this is the case for chrM in hg19:
hg19 <- getChromInfoFromUCSC("hg19", map.NCBI=TRUE)
hg19[is.na(hg19$NCBI.SequenceName), ]

## Map the hg19 sequences to the Ensembl sequence names:
getChromInfoFromUCSC("hg19", add.ensembl.col=TRUE)

## List of UCSC genome assemblies currently registered in the package:
registered_UCSC_genomes()
```

```

## -----
## B. USING getChromInfoFromUCSC() TO SET UCSC SEQUENCE NAMES ON THE
##   GRCh38 GENOME
## -----

## Load the BSgenome.Hsapiens.NCBI.GRCh38 package:
library(BSgenome)
genome <- getBSgenome("GRCh38") # this loads the
                                # BSgenome.Hsapiens.NCBI.GRCh38 package
genome

## Get the chromosome info for the hg38 genome:
hg38_chrom_info <- getChromInfoFromUCSC("hg38", map.NCBI=TRUE)
ncbi2ucsc <- setNames(hg38_chrom_info$chrom,
                      hg38_chrom_info$NCBI.SequenceName)

## Set the UCSC sequence names on 'genome':
seqlevels(genome) <- ncbi2ucsc[seqlevels(genome)]
genome

## Sanity check: check that the sequence lengths in 'genome' are the same
## as in 'hg38_chrom_info':
m <- match(seqlevels(genome), hg38_chrom_info$chrom)
stopifnot(identical(unname(seqlengths(genome)), hg38_chrom_info$size[m]))

```

loadTaxonomyDb

Return a data.frame that lists the known taxonomy IDs and their corresponding organisms.

Description

NCBI maintains a collection of unique taxonomy IDs and pairs these with associated genus and species designations. This function returns the set of pre-processed values that we use to check that something is a valid Taxonomy ID (or organism).

Usage

```
loadTaxonomyDb()
```

Value

A data frame with 1 row per genus/species designation and three columns. The 1st column is the taxonomy ID. The second column is the genus and the third is the species name.

Author(s)

Marc Carlson

Examples

```
## get the data
taxdb <- loadTaxonomyDb()
tail(taxdb)
## which can then be searched etc.
taxdb[grepl('yoelii', taxdb$species), ]
```

mapGenomeBuilds

Mapping between UCSC and Ensembl Genome Builds

Description

genomeBuilds lists the available genomes for a given species while mapGenomeBuilds maps between UCSC and Ensembl genome builds.

Usage

```
genomeBuilds(organism, style = c("UCSC", "Ensembl"))
mapGenomeBuilds(genome, style = c("UCSC", "Ensembl"))
listOrganisms()
```

Arguments

organism	A character vector of common names or organism
genome	A character vector of genomes equivalent to UCSC version or Ensembl Assemblies
style	A single value equivalent to "UCSC" or "Ensembl" specifying the output genome

Details

genomeBuilds lists the currently available genomes for a given list of organisms. The genomes can be shown as "UCSC" or "Ensembl" IDs determined by style. organism must be specified as a character vector and match common names (i.e "Dog", "Mouse") or organism name (i.e "Homo sapiens", "Mus musculus"). A list of available organisms can be shown using listOrganisms().

mapGenomeBuilds provides a mapping between "UCSC" builds and "Ensembl" builds. genome must be specified as a character vector and match either a "UCSC" ID or an "Ensembl" Id. genomeBuilds can be used to get a list of available build Ids for a given organism. NA's may be present in the output. This would occur when the current genome build removed a previously defined genome for an organism.

In both functions, if style is not specified, "UCSC" is used as default.

Value

A data.frame of builds for a given organism or genome in the specified style. If style == "UCSC", ucscID, ucscDate and ensemblID are given. If style == "Ensembl", ensemblID, ensemblVersion, ensemblDate, and ucscID are given. The opposing ID is given so that it is possible to distinguish between many-to-one mappings.

References

UCSC genome builds <https://genome.ucsc.edu/FAQ/FAQreleases.html> Ensembl genome builds <http://useast.ensembl.org/info/website/archives/assembly.html>

Examples

```
listOrganisms()

genomeBuilds("mouse")
genomeBuilds(c("Mouse", "dog", "human"), style="Ensembl")

mapGenomeBuilds(c("canFam3", "GRCm38", "mm9"))
mapGenomeBuilds(c("canFam3", "GRCm38", "mm9"), style="Ensembl")
```

rankSeqlevels

Assign sequence IDs to sequence names

Description

rankSeqlevels assigns a unique ID to each unique sequence name in the input vector. The returned IDs span 1:N where N is the number of unique sequence names in the input vector.

orderSeqlevels is similar to rankSeqlevels except that the returned vector contains the order instead of the rank.

Usage

```
rankSeqlevels(seqnames, X.is.sexchrom=NA)
orderSeqlevels(seqnames, X.is.sexchrom=NA)
```

Arguments

seqnames A character vector or factor containing sequence names.

X.is.sexchrom A logical indicating whether X refers to the sexual chromosome or to chromosome with Roman Numeral X. If NA, rankSeqlevels does its best to "guess".

Value

An integer vector of the same length as seqnames that tries to reflect the “natural” order of seqnames, e.g., chr1, chr2, chr3, ...

The values in the returned vector span 1:N where N is the number of unique sequence names in the input vector.

Author(s)

H. Pagès for rankSeqlevels, orderSeqlevels added by Sonali Arora

See Also

- [sortSeqlevels](#) for sorting the sequence levels of an object in "natural" order.

Examples

```
library(BSgenome.Scerevisiae.UCSC.sacCer2)
rankSeqlevels(seqnames(Scerevisiae))
rankSeqlevels(seqnames(Scerevisiae)[c(1:5,5:1)])

newchr <- paste0("chr",c(1:3,6:15,4:5,16:22))
newchr
orderSeqlevels(newchr)
rankSeqlevels(newchr)
```

seqinfo

Accessing/modifying sequence information

Description

A set of generic functions for getting/setting/modifying the sequence information stored in an object.

Usage

```
seqinfo(x)
seqinfo(x,
        new2old=NULL,
        pruning.mode=c("error", "coarse", "fine", "tidy")) <- value

seqnames(x)
seqnames(x) <- value

seqlevels(x)
seqlevels(x,
          pruning.mode=c("error", "coarse", "fine", "tidy")) <- value
sortSeqlevels(x, X.is.sexchrom=NA)
```

```

seqlevelsInUse(x)
seqlevels0(x)

seqlengths(x)
seqlengths(x) <- value

isCircular(x)
isCircular(x) <- value

genome(x)
genome(x) <- value

```

Arguments

x	Any object containing sequence information i.e. with a <code>seqinfo()</code> component.
new2old	<p>The <code>new2old</code> argument allows the user to rename, drop, add and/or reorder the "sequence levels" in <code>x</code>.</p> <p><code>new2old</code> can be <code>NULL</code> or an integer vector with one element per entry in <code>Seqinfo</code> object value (i.e. <code>new2old</code> and <code>value</code> must have the same length) describing how the "new" sequence levels should be mapped to the "old" sequence levels, that is, how the entries in <code>value</code> should be mapped to the entries in <code>seqinfo(x)</code>. The values in <code>new2old</code> must be ≥ 1 and $\leq \text{length}(\text{seqinfo}(x))$. NAs are allowed and indicate sequence levels that are being added. Old sequence levels that are not represented in <code>new2old</code> will be dropped, but this will fail if those levels are in use (e.g. if <code>x</code> is a <code>GRanges</code> object with ranges defined on those sequence levels) unless a pruning mode is specified via the <code>pruning.mode</code> argument (see below).</p> <p>If <code>new2old=NULL</code>, then sequence levels can only be added to the existing ones, that is, <code>value</code> must have at least as many entries as <code>seqinfo(x)</code> (i.e. $\text{length}(\text{values}) \geq \text{length}(\text{seqinfo}(x))$) and also <code>seqlevels(values)[seq_len(length(seqlevels(x)))]</code> must be identical to <code>seqlevels(x)</code>.</p>

Note that most of the times it's easier to proceed in 2 steps:

1. First align the `seqlevels` on the left (`seqlevels(x)`) with the `seqlevels` on the right.
2. Then call `seqinfo(x) <- value`. Because `seqlevels(x)` and `seqlevels(value)` now are identical, there's no need to specify `new2old`.

This 2-step approach will typically look like this:

```

seqlevels(x) <- seqlevels(value) # align seqlevels
seqinfo(x) <- seqinfo(value) # guaranteed to work

```

Or, if `x` has `seqlevels` not in `value`, it will look like this:

```

seqlevels(x, pruning.mode="coarse") <- seqlevels(value)
seqinfo(x) <- seqinfo(value) # guaranteed to work

```

The `pruning.mode` argument will control what happens to `x` when some of its `seqlevels` get dropped. See below for more information.

pruning.mode	<p>When some of the seqlevels to drop from <code>x</code> are in use (i.e. have ranges on them), the ranges on these sequences need to be removed before the seqlevels can be dropped. We call this <i>pruning</i>. The <code>pruning.mode</code> argument controls how to <i>prune</i> <code>x</code>. Four pruning modes are currently defined: "error", "coarse", "fine", and "tidy". "error" is the default. In this mode, no pruning is done and an error is raised. The other pruning modes do the following:</p> <ul style="list-style-type: none"> • "coarse": Remove the elements in <code>x</code> where the seqlevels to drop are in use. Typically reduces the length of <code>x</code>. Note that if <code>x</code> is a list-like object (e.g. GRangesList, GAlignmentPairs, or GAlignmentsList), then any list element in <code>x</code> where at least one of the sequence levels to drop is in use is <i>fully</i> removed. In other words, when <code>pruning.mode="coarse"</code>, the <code>seqlevels</code> setter will keep or remove <i>full list elements</i> and not try to change their content. This guarantees that the exact ranges (and their order) inside the individual list elements are preserved. This can be a desirable property when the list elements represent compound features like exons grouped by transcript (stored in a GRangesList object as returned by <code>exonsBy(, by="tx")</code>), or paired-end or fusion reads, etc... • "fine": Supported on list-like objects only. Removes the ranges that are on the sequences to drop. This removal is done within each list element of the original object <code>x</code> and doesn't affect its length or the order of its list elements. In other words, the pruned object is guaranteed to be <i>parallel</i> to the original object. • "tidy": Like the "fine" pruning above but also removes the list elements that become empty as the result of the pruning. Note that this pruning mode is particularly well suited on a GRangesList object that contains transcripts grouped by gene, as returned by <code>transcriptsBy(, by="gene")</code>. Finally note that, as a convenience, this pruning mode is supported on non list-like objects (e.g. GRanges or GAlignments objects) and, in this case, is equivalent to the "coarse" mode. <p>See the "B. DROP SEQLEVELS FROM A LIST-LIKE OBJECT" section in the examples below for an extensive illustration of these pruning modes.</p>
value	<p>Typically a Seqinfo object for the <code>seqinfo</code> setter.</p> <p>Either a named or unnamed character vector for the <code>seqlevels</code> setter.</p> <p>A vector containing the sequence information to store for the other setters.</p>
<code>X.is.sexchrom</code>	<p>A logical indicating whether <code>X</code> refers to the sexual chromosome or to chromosome with Roman Numeral <code>X</code>. If <code>NA</code>, <code>sortSeqlevels</code> does its best to "guess".</p>

It all revolves around Seqinfo objects

The [Seqinfo](#) class plays a central role for the functions described in this man page because:

1. All these functions (except `seqinfo`, `seqlevelsInUse`, and `seqlevels0`) work on a [Seqinfo](#) object.
2. For classes that implement it, the `seqinfo` getter should return a [Seqinfo](#) object.
3. Default `seqlevels`, `seqlengths`, `isCircular`, and `genome` getters and setters are provided. By default, `seqlevels(x)` does `seqlevels(seqinfo(x))`, `seqlengths(x)` does `seqlengths(seqinfo(x))`,

`isCircular(x)` does `isCircular(seqinfo(x))`, and `genome(x)` does `genome(seqinfo(x))`. So any class with a `seqinfo` getter will have all the above getters work out-of-the-box. If, in addition, the class defines a `seqinfo` setter, then all the corresponding setters will also work out-of-the-box.

Examples of containers that have a `seqinfo` getter and setter:

- the [GRanges](#) and [GRangesList](#) classes in the **GenomicRanges** package;
- the [SummarizedExperiment](#) class in the **SummarizedExperiment** package;
- the [GAlignments](#), [GAlignmentPairs](#), and [GAlignmentsList](#) classes in the **GenomicAlignments** package;
- the [TxDb](#) class in the **GenomicFeatures** package;
- the [BSgenome](#) class in the **BSgenome** package;
- and more...

Note

The full list of methods defined for a given generic function can be seen with e.g. `showMethods("seqinfo")` or `showMethods("seqnames")` (for the getters), and `showMethods("seqinfo<-")` or `showMethods("seqnames<-")` (for the setters a.k.a. *replacement methods*). Please be aware that this shows only methods defined in packages that are currently attached.

The **GenomicRanges** package defines `seqinfo` and `seqinfo<-` methods for these low-level data types: [List](#) and [IntegerRangesList](#). Those objects do not have the means to formally store sequence information. Thus, the wrappers simply store the [Seqinfo](#) object within `metadata(x)`. Initially, the metadata is empty, so there is some effort to generate a reasonable default [Seqinfo](#). The names of any [List](#) are taken as the `seqnames`, and the universe of [IntegerRangesList](#) is taken as the genome.

Examples

```
## -----
## A. BASIC USAGE OF THE seqlevels() GETTER AND SETTER
## -----
## Operations between 2 or more objects containing genomic ranges (e.g.
## finding overlaps, comparing, or matching) only make sense if the
## operands have the same seqlevels. So before performing such
## operations, it is often necessary to adjust the seqlevels in
## the operands so that they all have the same seqlevels. This is
## typically done with the seqlevels() setter. The setter can be used
## to rename, drop, add and/or reorder seqlevels of an object. The
## examples below show how to modify the seqlevels of a GRanges object
## but the same would apply to any object containing sequence
## information (i.e. with a seqinfo() component).
library(GenomicRanges)

gr <- GRanges(rep(c("chr2", "chr3", "chrM"), 2), IRanges(1:6, 10))

## Add new seqlevels:
seqlevels(gr) <- c("chr1", seqlevels(gr), "chr4")
seqlevels(gr)
seqlevelsInUse(gr)

## Reorder existing seqlevels:
seqlevels(gr) <- rev(seqlevels(gr))
seqlevels(gr)

## Drop all unused seqlevels:
seqlevels(gr) <- seqlevelsInUse(gr)

## Drop some seqlevels in use:
seqlevels(gr, pruning.mode="coarse") <- setdiff(seqlevels(gr), "chr3")
gr

## Rename, add, and reorder the seqlevels all at once:
seqlevels(gr) <- c("chr1", chr2="chr2", chrM="Mitochondrion")
seqlevels(gr)

## -----
## B. DROP SEQLEVELS FROM A LIST-LIKE OBJECT
## -----

grl0 <- GRangesList(A=GRanges("chr2", IRanges(3:2, 5)),
                   B=GRanges(c("chr2", "chrMT"), IRanges(7:6, 15)),
                   C=GRanges(c("chrY", "chrMT"), IRanges(17:16, 25)),
                   D=GRanges())

grl0

grl1 <- grl0
seqlevels(grl1, pruning.mode="coarse") <- c("chr2", "chr5")
grl1 # grl0[[2]] was fully removed! (even if it had a range on chr2)
```

```

## If what is desired is to remove the 2nd range in grl0[[2]] only (i.e.
## the chrMT:6-15 range), or, more generally speaking, to remove the
## ranges within each list element that are located on the seqlevels to
## drop, then use pruning.mode="fine" or pruning.mode="tidy":
grl2 <- grl0
seqlevels(grl2, pruning.mode="fine") <- c("chr2", "chr5")
grl2 # grl0[[2]] not removed, but chrMT:6-15 range removed from it

## Like pruning.mode="fine" but also removes grl0[[3]].

Description

A Seqinfo object is used to store basic information about a set of genomic sequences, typically chromosomes, but not necessarily.

Details

A Seqinfo object has one entry per sequence. Each entry contains the following information about the sequence:

- The sequence name (a.k.a. the *seqlevel*) e.g. "chr1".
- The sequence length.
- The sequence *circularity flag*. This is a logical indicating whether the sequence is circular (TRUE) or linear (FALSE).
- Which genome the sequence belongs to e.g. "hg19".

All entries must contain at least the sequence name. The other information is optional. In addition, the *seqnames* in a given Seqinfo object must be unique, that is, the object is not allowed to have two entries with the same sequence name.

Note that Seqinfo objects are usually not used as standalone objects but are instead typically found inside higher level objects like [GRanges](#) or [TxDb](#) objects. These higher level objects will generally provide a seqinfo() accessor for getting/setting their Seqinfo component.

Constructor

Seqinfo(seqnames, seqlengths=NA, isCircular=NA, genome=NA): Create a Seqinfo object and populate it with the supplied data.

One special form of calling the Seqinfo() constructor is to specify only the genome argument and set it to the name of an NCBI assembly (e.g. Seqinfo(genome="GRCh38.p13")) or UCSC genome (e.g. Seqinfo(genome="hg38")), in which case the sequence information is fetched from NCBI or UCSC. See Examples section below for some examples.

Accessor methods

In the code snippets below, x is a Seqinfo object.

length(x): Return the number of sequences in x.

seqnames(x), seqnames(x) <- value: Get/set the names of the sequences in x. Those names must be non-NA, non-empty and unique. They are also called the *sequence levels* or the *keys* of the Seqinfo object.

Note that, in general, the end user should not try to alter the sequence levels with seqnames(x) <- value. The recommended way to do this is with seqlevels(x) <- value as described below.

names(x), names(x) <- value: Same as seqnames(x) and seqnames(x) <- value.

seqlevels(x): Same as seqnames(x).

`seqlevels(x) <- value`: Can be used to rename, drop, add and/or reorder the sequence levels. `value` must be either a named or unnamed character vector. When `value` has names, the names only serve the purpose of mapping the new sequence levels to the old ones. Otherwise (i.e. when `value` is unnamed) this mapping is implicitly inferred from the following rules:

(1) If the number of new and old levels are the same, and if the positional mapping between the new and old levels shows that some or all of the levels are being renamed, and if the levels that are being renamed are renamed with levels that didn't exist before (i.e. are not present in the old levels), then `seqlevels(x) <- value` will just rename the sequence levels. Note that in that case the result is the same as with `seqnames(x) <- value` but it's still recommended to use `seqlevels(x) <- value` as it is safer.

(2) Otherwise (i.e. if the conditions for (1) are not satisfied) `seqlevels(x) <- value` will consider that the sequence levels are not being renamed and will just perform `x <- x[value]`.

See below for some examples.

`seqlengths(x)`, `seqlengths(x) <- value`: Get/set the length for each sequence in `x`.

`isCircular(x)`, `isCircular(x) <- value`: Get/set the circularity flag for each sequence in `x`.

`genome(x)`, `genome(x) <- value`: Get/set the genome identifier or assembly name for each sequence in `x`.

Subsetting

In the code snippets below, `x` is a Seqinfo object.

`x[i]`: A Seqinfo object can be subsetted only by name i.e. `i` must be a character vector. This is a convenient way to drop/add/reorder the entries in a Seqinfo object.

See below for some examples.

Coercion

In the code snippets below, `x` is a Seqinfo object.

`as.data.frame(x)`: Turns `x` into a data frame.

Combining Seqinfo objects

We provide no `c()` or `rbind()` methods for Seqinfo objects. This is because these operations would be expected to return an object of length `length(x) + length(y)` obtained by appending the entries from input object `y` to those from input object `x`. Such behavior would imply that the returned Seqinfo object is not guaranteed to contain unique seqnames, which is a requirement for Seqinfo objects.

So instead, a `merge()` method is provided.

In the code snippet below, `x` and `y` are Seqinfo objects.

`merge(x, y, ...)`: Merge `x` and `y` into a single Seqinfo object where the keys (i.e. the seqnames) are `union(seqnames(x), seqnames(y))`. If an entry in `y` has the same key as an entry in `x`, and if the two entries contain compatible information (NA values are treated as wildcards i.e. they're compatible with anything), then the two entries are merged into a single entry in the result. If they cannot be merged (because they contain different seqlengths, and/or circularity

flags, and/or genome identifiers), then an error is raised. In addition to check for incompatible sequence information, `merge(x, y)` also compares `seqnames(x)` with `seqnames(y)` and issues a warning if each of them has names not in the other. The purpose of these checks is to try to detect situations where the user might be combining or comparing objects that use different underlying genomes.

Note that `merge()` can take more than two `Seqinfo` objects, in which case the objects are merged from left to right e.g.

```
merge(x1, x2, x3, x4)
```

is equivalent to

```
merge(merge(merge(x1, x2), x3), x4)
```

`intersect(x, y)`: Finds the intersection between two `Seqinfo` objects by merging them and subsetting for the intersection of their sequence names. This makes it easy to avoid warnings about each objects not being a subset of the other one during overlap operations.

A convenience wrapper, `checkCompatibleSeqinfo()`, is provided for checking whether 2 objects have compatible `seqinfo` components or not. `checkCompatibleSeqinfo(x, y)` is equivalent to `merge(seqinfo(x), seqinfo(y))` so will work on any objects `x` and `y` that support [seqinfo\(\)](#).

Seqinfo(genome="canFam3")
Seqinfo(genome="musFur1")
Seqinfo(genome="galGal6")
Seqinfo(genome="dm6")
Seqinfo(genome="ce11")
Seqinfo(genome="sacCer3")
}

## -----
## B. BASIC MANIPULATION OF A Seqinfo OBJECT
## -----

## Note that all the arguments (except 'genome') must have the
## same length. 'genome' can be of length 1, whatever the lengths
## of the other arguments are.
x <- Seqinfo(seqnames=c("chr1", "chr2", "chr3", "chrM"),
             seqlengths=c(100, 200, NA, 15),
             isCircular=c(NA, FALSE, FALSE, TRUE),
             genome="toy")

x

## Accessors:
length(x)
seqnames(x)
names(x)
seqlevels(x)
seqlengths(x)
isCircular(x)
genome(x)

## Get a compact summary:
summary(x)

## Subset by names:
x[c("chrY", "chr3", "chr1")]

## Rename, drop, add and/or reorder the sequence levels:
xx <- x
seqlevels(xx) <- sub("chr", "ch", seqlevels(xx)) # rename
xx
seqlevels(xx) <- rev(seqlevels(xx)) # reorder
xx
seqlevels(xx) <- c("ch1", "ch2", "chY") # drop/add/reorder
xx
seqlevels(xx) <- c(chY="Y", ch1="1", "22") # rename/reorder/drop/add

```

```

xx

## -----
## C. MERGING 2 Seqinfo OBJECTS
## -----

y <- Seqinfo(seqnames=c("chr3", "chr4", "chrM"),
              seqlengths=c(300, NA, 15))

y

## This issues a warning:
merge(x, y) # the entries for chr3 and chrM contain information merged
            # from the corresponding entries in 'x' and 'y'

## To get rid of the above warning, either use suppressWarnings() or
## set the genome on 'y':
suppressWarnings(merge(x, y))
genome(y) <- genome(x)
merge(x, y)

## Note that, strictly speaking, merging 2 Seqinfo objects is not
## a commutative operation, i.e., in general 'z1 <- merge(x, y)'
## is not identical to 'z2 <- merge(y, x)'. However 'z1' and 'z2'
## are guaranteed to contain the same information (i.e. the same
## entries, but typically not in the same order):
merge(y, x)

## This contradicts what 'x' says about circularity of chr3 and chrM:
isCircular(y)[c("chr3", "chrM")] <- c(TRUE, FALSE)
y
if (interactive()) {
  merge(x, y) # raises an error
}

## Sanity checks:
stopifnot(identical(x, merge(x, Seqinfo())))
stopifnot(identical(x, merge(Seqinfo(), x)))
stopifnot(identical(x, merge(x, x)))

library(GenomicRanges)
gr1 <- GRanges("chr3:15-25", seqinfo=x)
gr2 <- GRanges("chr3:105-115", seqinfo=y)
if (interactive()) {
  checkCompatibleSeqinfo(gr1, gr2) # raises an error
}

```

Description

Keep, drop or rename seqlevels in objects with a [Seqinfo](#) class.

Usage

```
keepSeqlevels(x, value, pruning.mode=c("error", "coarse", "fine", "tidy"))
dropSeqlevels(x, value, pruning.mode=c("error", "coarse", "fine", "tidy"))
renameSeqlevels(x, value)
restoreSeqlevels(x)
standardChromosomes(x, species=NULL)
keepStandardChromosomes(x, species=NULL,
                        pruning.mode=c("error", "coarse", "fine", "tidy"))
```

Arguments

x	Any object having a Seqinfo class in which the seqlevels will be kept, dropped or renamed.
value	A named or unnamed character vector. Names are ignored by keepSeqlevels and dropSeqlevels. Only the values in the character vector dictate which seqlevels to keep or drop. In the case of renameSeqlevels, the names are used to map new sequence levels to the old (names correspond to the old levels). When value is unnamed, the replacement vector must the same length and in the same order as the original seqlevels(x).
pruning.mode	See ?seqinfo for a description of the pruning modes.
species	The genus and species of the organism. Supported species can be seen with names(genomeStyles()).

Details

Matching and overlap operations on range objects often require that the seqlevels match before a comparison can be made (e.g., findOverlaps). keepSeqlevels, dropSeqlevels and renameSeqlevels are high-level convenience functions that wrap the low-level seqlevels setter.

- keepSeqlevels, dropSeqlevels: Subsetting operations that modify the size of x. keepSeqlevels keeps only the seqlevels in value and removes all others. dropSeqlevels drops the levels in value and retains all others. If value does not match any seqlevels in x an empty object is returned.
When x is a GRangesList it is possible to have 'mixed' list elements that have ranges from different chromosomes. keepSeqlevels will not keep 'mixed' list elements
- renameSeqlevels: Rename the seqlevels in x to those in value. If value is a named character vector, the names are used to map the new seqlevels to the old. When value is unnamed, the replacement vector must be the same length and in the same order as the original seqlevels(x).
- restoreSeqlevels: Perform seqlevels(txdb) <- seqlevels0(txdb), that is, restore the seqlevels in x back to the original values. Applicable only when x is a TxDb object.

- **standardChromosomes**: Lists the 'standard' chromosomes defined as sequences in the assembly that are not scaffolds; also referred to as an 'assembly molecule' in NCBI. `standardChromosomes` attempts to detect the `seqlevel` style and if more than one style is matched, e.g., 'UCSC' and 'Ensembl', the first is chosen.

`x` must have a `Seqinfo` object. `species` can be specified as a character string; supported species are listed with `names(genomeStyles())`.

When `x` contains `seqlevels` from multiple organisms all those considered standard will be kept. For example, if `seqlevels` are "chr1" and "chr3R" from human and fly both will be kept. If `species="Homo sapiens"` is specified then only "chr1" is kept.

- **keepStandardChromosomes**: Subsetting operation that returns only the 'standard' chromosomes.

`x` must have a `Seqinfo` object. `species` can be specified as a character string; supported species are listed with `names(genomeStyles())`.

When `x` contains `seqlevels` from multiple organisms all those considered standard will be kept. For example, if `seqlevels` are "chr1" and "chr3R" from human and fly both will be kept. If `species="Homo sapiens"` is specified then only "chr1" is kept.

Value

The `x` object with `seqlevels` removed or renamed. If `x` has no `seqlevels` (empty object) or no replacement values match the current `seqlevels` in `x` the unchanged `x` is returned.

```

seqlevelsStyle	<i>Conveniently rename the seqlevels of an object according to a given style</i>
----------------	--

Description

The `seqlevelsStyle` getter and setter can be used to get the current `seqlevels` style of an object and to rename its `seqlevels` according to a given style.

Usage

```

seqlevelsStyle(x)
seqlevelsStyle(x) <- value

## Related low-level utilities:
genomeStyles(species)
extractSeqlevels(species, style)
extractSeqlevelsByGroup(species, style, group)
mapSeqlevels(seqnames, style, best.only=TRUE, drop=TRUE)
seqlevelsInGroup(seqnames, group, species, style)

```

Arguments

<code>x</code>	The object from/on which to get/set the <code>seqlevels</code> style. <code>x</code> must have a <code>seqlevels</code> method or be a character vector.
<code>value</code>	A single character string that sets the <code>seqlevels</code> style for <code>x</code> .
<code>species</code>	The genus and species of the organism in question separated by a single space. Don't forget to capitalize the genus.
<code>style</code>	a character vector with a single element to specify the style.
<code>group</code>	Group can be 'auto' for autosomes, 'sex' for sex chromosomes/allosomes, 'circular' for circular chromosomes. The default is 'all' which returns all the chromosomes.

<code>best.only</code>	if TRUE (the default), then only the "best" sequence renaming maps (i.e. the rows with less NAs) are returned.
<code>drop</code>	if TRUE (the default), then a vector is returned instead of a matrix when the matrix has only 1 row.
<code>seqnames</code>	a character vector containing the labels attached to the chromosomes in a given genome for a given style. For example : For <i>Homo sapiens</i> , NCBI style - they are "1","2","3",..., "X","Y","MT"

Details

`seqlevelsStyle(x)`, `seqlevelsStyle(x) <- value`: Get the current seqlevels style of an object, or rename its seqlevels according to the supplied style.

`genomeStyles`: Different organizations have different naming conventions for how they name the biologically defined sequence elements (usually chromosomes) for each organism they support. The `Seqnames` package contains a database that defines these different conventions.

`genomeStyles()` returns the list of all supported seqname mappings, one per supported organism. Each mapping is represented as a data frame with 1 column per seqname style and 1 row per chromosome name (not all chromosomes of a given organism necessarily belong to the mapping).

`genomeStyles(species)` returns a data.frame only for the given organism with all its supported seqname mappings.

`extractSeqlevels`: Returns a character vector of the seqnames for a single style and species.

`extractSeqlevelsByGroup`: Returns a character vector of the seqnames for a single style and species by group. Group can be 'auto' for autosomes, 'sex' for sex chromosomes/ allosomes, 'circular' for circular chromosomes. The default is 'all' which returns all the chromosomes.

`mapSeqlevels`: Returns a matrix with 1 column per supplied sequence name and 1 row per sequence renaming map compatible with the specified style. If `best.only` is TRUE (the default), only the "best" renaming maps (i.e. the rows with less NAs) are returned.

`seqlevelsInGroup`: It takes a character vector along with a group and optional style and species. If group is not specified, it returns "all" or standard/top level seqnames. Returns a character vector of seqnames after subsetting for the group specified by the user. See examples for more details.

Value

For `seqlevelsStyle`: A single string containing the style of the seqlevels in `x`, or a character vector containing the styles of the seqlevels in `x` if the current style cannot be determined unambiguously. Note that this information is not stored in `x` but inferred from its seqlevels using a heuristic helped by a seqlevels style database stored in the **GenomeInfoDb** package. If the underlying genome is known (i.e. if `unique(genome(x))` is not NA), the name of the genome or assembly (e.g. `ce11` or `WBcel1235`) is also used by the heuristic.

For `extractSeqlevels`, `extractSeqlevelsByGroup` and `seqlevelsInGroup`: A character vector of seqlevels for given supported species and group.

For `mapSeqlevels`: A matrix with 1 column per supplied sequence name and 1 row per sequence renaming map compatible with the specified style.

For `genomeStyle`: If `species` is specified returns a data.frame containing the seqlevels style and its mapping for a given organism. If `species` is not specified, a list is returned with one list per species containing the seqlevels style with the corresponding mappings.
