Package 'minet'

April 12, 2018

Title Mutual Information NETworks

Version 3.36.0

Date 2014-07

Author Patrick E. Meyer, Frederic Lafitte, Gianluca Bontempi

Description This package implements various algorithms for inferring mutual information networks from data.

aracne   *Algorithm for the Reconstruction of Accurate Cellular NEtworks*

Description

This function takes the mutual information matrix as input in order to return the infered network according to the Aracne algorithm. This algorithm applies the data processing inequality to all triplets of nodes in order to remove the least significant edge in each triplet.

Usage

```
aracne( mim, eps=0 )
```

Arguments

mim   A square matrix whose i,j th element is the mutual information between variables Xi and Xj - see `build.mim`.

eps   Numeric value indicating the threshold used when removing an edge : for each triplet of nodes (i,j,k), the weakest edge, say (ij), is removed if its weight is below min{(ik),(jk)}-eps - see references.

Details

The Aracne procedure starts by assigning to each pair of nodes a weight equal to their mutual information. Then, the weakest edge of each triplet is interpreted as an indirect interaction and is removed if the difference between the two lowest weights is above a threshold eps.

Value

aracne returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following command:
plot(as(returned.matrix ,"graphNEL"))

build.mim   *Build Mutual Information Matrix*

Description

`build.mim` takes the dataset as input and computes the mutual information beetween all pair of variables according to the mutual inforamtion estimator `estimator`. The results are saved in the mutual information matrix (MIM), a square matrix whose (i,j) element is the mutual information between variables X_i and X_j.

Usage

```
build.mim(dataset, estimator = "spearman", disc = "none", nbins = sqrt(NROW(dataset)))
```

Arguments

dataset	data.frame containing gene expression data or any dataset where columns contain variables/features and rows contain outcomes/samples.
estimator	The name of the entropy estimator to be used. The package can use the four mutual information estimators implemented in the package "infotheo": "mi.empirical", "mi.mm", "mi.shrink", "mi.sg" and three estimators based on correlation: "pearson","spearman","kendall"(default:"spearman") - see details.
disc	The name of the discretization method to be used with one of the discrete estimators: "none", "equalfreq", "equalwidth" or "globalequalwidth" (default : "none") - see infotheo package.
nbins	Integer specifying the number of bins to be used for the discretization if disc is different from "none". By default the number of bins is set to $\sqrt{m}$ where m is the number of samples.

Details

- "mi.empirical" : This estimator computes the entropy of the empirical probability distribution.
- "mi.mm" : This is the Miller-Madow asymptotic bias corrected empirical estimator.
- "mi.shrink" : This is a shrinkage estimate of the entropy of a Dirichlet probability distribution.
- "mi.sg" : This is the Schurmann-Grassberger estimate of the entropy of a Dirichlet probability distribution.
- "pearson" : This computes mutual information for normally distributed variable.
- "spearman" : This computes mutual information for normally distributed variable using Spearman's correlation instead of Pearson's correlation.
- "kendall" : This computes mutual information for normally distributed variable using Kendall's correlation instead of Pearson's correlation.

Value

`build.mim` returns the mutual information matrix.

mim <- build.mim(syn.data,estimator="spearman")
```

---

clr   *Context Likelihood or Relatedness Network*

Description

clr takes the mutual information matrix as input in order to return the infered network - see details.

Usage

```
clr( mim, skipDiagonal=1 )
```

Arguments

mim	A square matrix whose i,j th element is the mutual information between variables Xi and Xj - see build.mim.
skipDiagonal	Skips the diagonal in the calculation of the mean and sd, default=1.

Details

The CLR algorithm is an extension of relevance network. Instead of considering the mutual information $I(X_i; X_j)$ between features X_i and X_j, it takes into account the score $\sqrt{z_i^2 + z_j^2}$, where

$$z_i = \max \left\{ 0, \frac{I(X_i; X_j) - \mu_i}{\sigma_i} \right\}$$

and μ_i and σ_i are, respectively, the mean and the standard deviation of the empirical distribution of the mutual information values $I(X_i; X_k)$, k=1,...,n.

Value

clr returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following comand plot(as(returned.matrix ,"graphNEL"))

minet   *Mutual Information Network*

Description

For a given dataset, minet infers the network in two steps. First, the mutual information between all pairs of variables in dataset is computed according to the estimator argument. Then the algorithm given by method considers the estimated mutual informations in order to build the network. This package is licensed under a Creative Commons Attribution-NonCommercial-ShareAlike 3.0 Unported License.

Usage

```
minet(dataset, method="mrnet", estimator="spearman", disc="none", nbins=sqrt(NROW(dataset)))
```

Arguments

dataset	data.frame where columns contain variables/features and rows contain outcomes/samples.
method	The name of the inference algorithm : "clr", "aracne", "mrnet" or "mrnetb" (default: "mrnet") - see references.
estimator	The name of an entropy estimator (or correlation) to be used for mutual information computation ("pearson","spearman","kendall" and from infotheo package:"mi.empirical", "mi.mm", "mi.shrink", "mi.sg"), (default: "spearman") . - see build.mim.
disc	The name of the discretization method to be used, if required by the estimator :"none" ,"equalfreq", "equalwidth" or "globalequalwidth" (default : "none") - see infotheo package.
nbins	Integer specifying the number of bins to be used for the discretization if disc is set properly. By default the number of bins is set to $\sqrt{N}$ where N is the number of samples.

Value

minet returns a matrix which is the weighted adjacency matrix of the network. The weights range from 0 to 1 and can be seen as a confidence measure on the presence of the arcs. In order to display the network, load the package Rgraphviz and use the following command:

plot(as(returned.matrix ,"graphNEL"))

mrnet   *Maximum Relevance Minimum Redundancy*

Description

mrnet takes the mutual information matrix as input in order to infer the network using the maximum relevance/minimum redundancy feature selection method - see details.

Usage

```
mrnet(mim)
```

Arguments

mim   A square matrix whose i,j th element is the mutual information between vari-
                    ables Xi and Xj - see build.mim.

Details

The MRNET approach consists in repeating a MRMR feature selection procedure for each variable of the dataset. The MRMR method starts by selecting the variable X_i having the highest mutual information with the target Y. In the following steps, given a set $\mathcal{S}$ of selected variables, the criterion updates $\mathcal{S}$ by choosing the variable X_k that maximizes $I(X_k; Y) - \frac{1}{|\mathcal{S}|} \sum_{X_i \in \mathcal{S}} I(X_k; X_i)$

The weight of each pair X_i, X_j will be the maximum score between the one computed when X_i is the target and the one computed when X_j is the target.

Value

mrnet returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following command:
plot(as(returned.matrix ,"graphNEL"))

mrnetb   *Maximum Relevance Minimum Redundancy Backward*

Description

mrnetb takes the mutual information matrix as input in order to infer the network using the maximum relevance/minimum redundancy criterion combined with a backward elimination and a sequential replacement - see references. This method is a variant of mrnet.

Usage

```
mrnetb(mim)
```

Arguments

mim   A square matrix whose i,j th element is the mutual information between variables Xi and Xj - see build.mim.

Value

mrnetb returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following command:
plot(as(returned.matrix ,"graphNEL"))

syn.data   *Simulated Gene Expression Data*

Description

Dataset containing 100 samples and 50 genes generated by the publicly available SynTReN generator using a yeast source network - see syn.net

Usage

```
data(syn.data)
```

Format

syn.data is a data frame containing 100 rows and 50 columns. Each row contains a microarray experiment and each column contains a gene.

Source

SynTReN 1.1.3 with source network : yeast_nn.sif

References

Tim Van den Bulcke, Koenraad Van Leemput, Bart Naudts, Piet van Remortel, Hongwu Ma, Alain Verschoren, Bart De Moor, and Kathleen Marchal. Syntren : a generator of synthetic gene expression dataset for design and analysis of structure learning algorithms. BMC Bioinformatics, 2006.

Examples

```
data(syn.data)
data(syn.net)
mim <- build.mim(syn.data,estimator="spearman")
infered.net <- mrnet(mim)
max(fscores(validate( infered.net, syn.net )))
```

---

syn.net   *SynTReN Source Network*

Description

This is the true underlying network used to generate the dataset loaded by `data(syn.data)` - see
`syn.data`.

Usage

```
data(syn.net)
```

Format

`syn.net` is a boolean adjacency matrix representing an undirected graph of 50 nodes.

Source

`syn.net` is the "yeast_nn.sif" source network from the SynTReN generator where all the variables/nodes not in `syn.data` were removed.

References

Tim Van den Bulcke, Koenraad Van Leemput, Bart Naudts, Piet van Remortel, Hongwu Ma, Alain Verschoren, Bart De Moor, and Kathleen Marchal. Syntren : a generator of synthetic gene expression dataset for design and analysis of structure learning algorithms. BMC Bioinformatics, 2006.

Examples

```
data(syn.data)
data(syn.net)
mim <- build.mim(syn.data,estimator="spearman")
infered.net <- mrnet(mim)
max(fscores(validate( infered.net, syn.net )))
```

---

validate   *Inference Validation*

Description

validate compares the infered network to the true underlying network for several threshold values and appends the resulting confusion matrices to the returned object.

Usage

```
validate(inet,tnet)
```

Arguments

inet   This is the infered network, a data.frame or matrix obtained by one of the functions minet, aracne, clr or mrnet .

tnet   The true underlying network. This network must have the same size and variable names as inet.

Details

The first network inet is compared to the true underlying network, tnet, in order to compute a confusion (adjacency) matrix. All the confusion matrices, obtained with different threshold values, are appended to the returned object. In the end the validate function returns a data.frame containing steps+1 confusion matrices.

Value

validate returns a data.frame whith four columns named thrsh, tp, fp, fn. These values are computed for each of the steps thresholds. Thus each row of the returned object contains the confusion matrix for a different threshold.

See Also

minet, vis.res

Examples

```
data(syn.data)
data(syn.net)
inf.net <- mrnet(build.mim(syn.data, estimator="spearman"))
table <- validate( inf.net, syn.net )
table <- validate( inf.net, syn.net )
```

---

vis.res *Visualize Results*

Description

A group of functions to plot precision-recall and ROC curves and to compute f-scores from the data.frame returned by the validate function.

Usage

```
pr(table)
rates(table)
fscores(table, beta=1)
show.pr(table,device=-1,...)
show.roc(table,device=-1,...)
auc.roc(table)
auc.pr(table)
```

Arguments

table
: This is the data.frame returned by the validate function where columns contain TP,FP,TN,FN values (confusion matrix) as well as the threshold value used - see validate.

beta
: Numeric used as the weight of the recall in the f-score formula - see details. The default value of this argument is 1, meaning precision as important as recall.

device
: The device to be used. This parameter allows the user to plot precision-recall and receiver operating characteristic curves for various inference algorithms on the same plotting window - see examples.

...
: arguments passed to plot

Details

A confusion matrix contains FP,TP,FN,FP values.

- "true positive rate" $tpr = \frac{TP}{TN+TP}$
- "false positive rate" $fpr = \frac{FP}{FN+FP}$
- "precision" $p = \frac{TP}{FP+TP}$
- "recall" $r = \frac{TP}{TP+FN}$
- "f-beta-score" $F_\beta = (1 + \beta)\frac{pr}{r+\beta p}$

Value

The function show.roc (show.pr) plots the ROC-curve (PR-curve) and returns the device associated with the plotting window.

The function auc.roc (auc.pr) computes the area under the ROC-curve (PR-curve) using the trapezoidal approximation.

The function pr returns a data.frame where steps is the number of thresholds used in the validation process. The first column contains precisions and the second recalls - see details.

The function `rates` also returns a data.frame where the first column contains true positive rates and the second column false positive rates - see details.

The function `fscores` returns fscores according to the confusion matrices contained in the 'table' argument - see details.
