Package 'openCyto'

April 16, 2019

Type Package

Title Hierarchical Gating Pipeline for flow cytometry data

Version 1.20.2

Date 2012-06-11

Author Mike Jiang, John Ramey, Greg Finak, Raphael Gottardo

Maintainer Mike Jiang <wjiang2@fhcrc.org>

Description This package is designed to facilitate the automated gating
methods in sequential way to mimic the manual gating strategy.

R topics documented:

.isPolyfunctional   *A function to tell wether a gating method is* polyFunctions

Description

A function to tell wether a gating method is polyFunctions

Usage

```
.isPolyfunctional(gm)
```

Arguments

gm   an object that extends gtMethod

.prior_flowClust1d   *Elicits data-driven priors from a flowSet object for a specified channel*

Description

We elicit data-driven prior parameters from a flowSet object for a specified channel. For each sample in the flowSet object, we apply a kernel-density estimator (KDE) and identify its local maxima (peaks). We then aggregate these peaks to elicit a prior parameters for each of K mixture components.

Usage

```
.prior_flowClust1d(flow_set, channel, K = NULL, hclust_height = NULL,
  clust_method = c("kmeans", "hclust"), hclust_method = "complete",
  artificial = NULL, nu0 = 4, w0 = 10, adjust = 2, min = -200,
  max = NULL, vague = TRUE)
```

Arguments

flow_set	a flowSet object
channel	the channel in the flowSet from which we elicit the prior parameters for the Student's t mixture
K	the number of mixture components to identify. By default, this value is NULL and determined automatically
hclust_height	the height of the hclust tree of peaks, where the should be cut By default, we use the median of the distances between adjacent peaks. If a value is specified, we pass it directly to cutree.
clust_method	the method used to cluster peaks together when for prior elicitation. By default, kmeans is used. However, if K is not specified, hclust will be used instead.
hclust_method	the agglomeration method used in the hierarchical clustering. This value is passed directly to hclust. Default is complete linkage.
artificial	a numeric vector containing prior means for artificial mixture components. The remaining prior parameters for the artificial components are copied directly from the most informative prior component elicited. If NULL (default), no artificial prior components are added.
nu0	prior degrees of freedom of the Student's t mixture components.
w0	the number of prior pseudocounts of the Student's t mixture components.
adjust	the bandwidth to use in the kernel density estimation. See density for more information.
min	a numeric value that sets the lower bound for data filtering. If NULL (default), no truncation is applied.
max	a numeric value that sets the upper bound for data filtering. If NULL (default), no truncation is applied.
vague	logical Whether to elicit a vague prior. If TRUE, we first calculate the median of standard deviations from all flowFrames. Then, we divide the overall standard deviation by the number of groups to the scale the standard deviation.

Details

Here, we outline the approach used for prior elicitation. First, we apply a KDE to each sample and extract all of its peaks (local maxima). It is important to note that different samples may have a different number of peaks. Our goal then is to align the peaks before aggregating the information across all samples. To do this, we utilize a technique similar to the peak probability contrasts (PPC) method from Tibshirani et al (2004). Effectively, we apply hierarchical clustering to the peaks from all samples to find clusters of peaks. We compute the sample mean and variance of the peaks within each cluster to elicit the prior means and its hyperprior variance, respectively, for a flowClust mixture component. We elicit the prior variance for each mixture component by first assigning the observations within each sample to the nearest prior mean. Then, we compute the variance of the observations within each cluster. Finally, we average the variances corresponding to each mixture component across all samples in the flowSet object.

Following Tibshirani et al. (2004), we cluster the peaks from each sample using complete-linkage hierarchical clustering. The linkage type can be changed via the hclust_method argument. This argument is passed directly to hclust.

To cluster the peaks, we must cut the hierarchical tree by selecting either a value for K or by providing a height of the tree to cut. By default, we cut the tree using as the height the median of the distances between adjacent peaks within each sample. This value can be changed via the

hclust_height argument and, if provided, will be passed to [cutree]. Also, by default, the number of mixture components K is NULL and is ignored. However, if K is provided, then it has priority over hclust_height and is passed instead directly to [cutree].

To ensure that the KDEs are smooth, we recommend that the bandwidth set in the adjust argument be sufficiently large. We have defaulted this value to 2. If the bandwidth is not large enough, the KDE may contain numerous bumps, resulting in erroneous peaks.

Value

list of prior parameters

References

Tibshirani, R et al. (2004), "Sample classification from protein mass spectrometry, by 'peak probability contrasts'," Bioinformatics, 20, 17, 3034-3044. http://bioinformatics.oxfordjournals.org/content/20/17/3034.

.prior_kmeans	*Elicits data-driven priors from a flowSet object for specified channels using the K-Means clustering algorithm*

Description

We elicit data-driven prior parameters from a flowSet object for specified channels. For each sample in the flowSet object, we apply kmeans to obtain K clusters. From each cluster, we determine its centroid and the sample covariance matrix. We then aggregate these two sample moments across all samples for each cluster.

Usage

```
.prior_kmeans(flow_set, channels, K, nu0 = 4, w0 = 10, nstart = 10,
  pct = 0.1, min = NULL, max = NULL, ...)
```

Arguments

flow_set	a flowSet object
channels	a character vector containing the channels in the flowSet from which we elicit the prior parameters for the Student's t mixture
K	the number of mixture components to identify
nu0	prior degrees of freedom of the Student's t mixture components.
w0	the number of prior pseudocounts of the Student's t mixture components.
nstart	number of random starts used by kmeans algorithm
pct	percentage of randomly selected cells in each flowFrame that is used to elicit the prior parameters. The value should must be greater than 0 and less than or equal to 1.
min	a numeric vector that sets the lower bounds for data filtering. If NULL (default), no truncation is applied.
max	a numeric vector that sets the upper bounds for data filtering. If NULL (default), no truncation is applied.
...	Additional arguments passed to kmeans

Details

Because the cluster labels returned from kmeans are arbitrary, we align the clusters based on the centroids that are closest to a randomly selected reference sample. We apply the Hungarian algorithm implemented using the solve_LSAP function from the clue package to assist with the alignment.

If each frame within flow_set has a large number of cells, the computational costs of kmeans can be a burden. We provide the option to randomly select pct, a percentage of the cells from each flow frame to which kmeans is applied.

Value

list of flowClust prior parameters

---

add,GatingHierarchy,ocRectangleGate-method
                    bypass the default flowWorkspace:::.addGate

---

Description

to support adding gate along with indices without loading flow data and computing

to support adding rectangleGate yet gating through boolean operations without loading flow data

Usage

```
## S4 method for signature 'GatingHierarchy,ocRectangleGate'
add(wf, action, recompute, ...)

## S4 method for signature 'GatingHierarchy,ocRectRefGate'
add(wf, action, recompute, ...)
```

Arguments

wf	GatingHierarchy see add in flowWorkspace package
action	ocRectangleGate or logicalFilterResult
recompute	logical see add in flowWorkspace package
...	see add in flowWorkspace package

Details

however it is proven that logical indices are too big to be efficiently passed around

---

add_pop   *apply a gating method to the* GatingSet

Description

When interacting with the existing gated data, this function provides the alternative way to interact with he GatingSet by supplying the gating description directly through arguments without the need to write the compelete csv gating template.

Usage

```
add_pop(gs, alias = "*", pop = "+", parent, dims = NA, gating_method,
  gating_args = NA, collapseDataForGating = NA, groupBy = NA,
  preprocessing_method = NA, preprocessing_args = NA,
  strip_extra_quotes = FALSE, ...)
```

Arguments

gs   GatingSet or GatingSetList

alias, pop, parent, dims, gating_method, gating_args, collapseDataForGating, groupBy, preprocess
                  see details in [gatingTemplate](#)

strip_extra_quotes

                  logical Extra quotes are added to strings by fread. This causes problems with
                  parsing R strings to expressions in some cases. Default FALSE for usual be-
                  haviour. TRUE should be passed if parsing gating_args fails.

...   other arguments

                  - mc.cores passed to multicore package for parallel computing
                  - parallel_type character specifying the parallel type. The valid options are
                    "none", "multicore", "cluster".
                  - cl cluster object passed to parallel package (when parallel_type is
                    "cluster")

Examples

```
## Not run:
 # add quad gates
 add_pop(gs, gating_method = "mindensity", dims = "CCR7,CD45RA", parent = "cd4-cd8+", pop = "CCR7+/-CD45RA+/-

# polyfunctional gates (boolean combinations of exsiting marginal gates)
add_pop(gs, gating_method = "polyFunctions", parent = "cd8", gating_args = "cd8/IFNg:cd8/IL2:cd8/TNFa")

#boolGate method
add_pop(gs, alias = "IL2orIFNg", gating_method = "boolGate", parent = "cd4", gating_args = "cd4/IL2|cd4/IFNg"

## End(Not run)
```

`as.data.table.gatingTemplate`

convert a gatingTemplate object to a data.table

Description

It is the inverse function of gatingTemplate constructor.

Usage

```
## S3 method for class 'gatingTemplate'
as.data.table(x, keep.rownames = FALSE)
```

Arguments

x   gatingTemplate object

keep.rownames   not used

Value

a data.table

`boolMethod-class`   *A class to represent a boolean gating method.*

Description

It extends `refGate` class.

`dims,gtMethod-method`   *get gating method dimensions*

Description

get gating method dimensions

Usage

```
## S4 method for signature 'gtMethod'
dims(x)
```

Arguments

x   gtMethod

dummyMethod-class   *A class to represent a dummy gating method that does nothing but serves as reference to be refered by other population*

Description

It is generated automatically by the csv template preprocessing to handle the gating function that returns multiple gates.

fcEllipsoidGate   *constuctor for* `fcEllipsoidGate`

Description

constuctor for `fcEllipsoidGate`

Usage

```
fcEllipsoidGate(x, priors, posts)
```

Arguments

x	a `ellipsoidGate` object
priors	a `list` storing priors
posts	a `list` storing posteriors

fcEllipsoidGate-class   *a concrete class that reprents the ellipsoidGate generated by flowClust*

Description

It stores priors and posteriors as well as the actual ellipsoidGate.

fcFilter-class   *a virtual class that represents the gating result generated by flowClust gating function*

Description

Bascially it extends flowCore 'filter classes to have extra slot to store priors and posteriors

---

fcFilterList   *constuctor for* fcFilterList

Description

constuctor for fcFilterList

Usage

```
fcFilterList(x)
```

Arguments

x   list of fcFilter (i.e. fcPolygonGate or fcRectangleGate)

---

fcFilterList-class   *a class that extends* filterList *class.*

Description

Each filter in the filterList must extends the fcFilter class

---

fcPolygonGate   *constuctor for* fcPolygonGate

Description

constuctor for fcPolygonGate

Usage

```
fcPolygonGate(x, priors, posts)
```

Arguments

x	a polygonGate object
priors	a list storing priors
posts	a list storing posteriors

---

fcPolygonGate-class   *a concrete class that reprents the polygonGate generated by flowClust*

Description

It stores priors and posteriors as well as the actual polygonGate.

fcRectangleGate	*constuctor for* fcRectangleGate

Description

constuctor for fcRectangleGate

Usage

```
fcRectangleGate(x, priors, posts)
```

Arguments

x	a rectangleGate object
priors	a list storing priors
posts	a list storing posteriors

fcRectangleGate-class	*a concrete class that reprents the rectangleGate generated by flow-Clust*

Description

It stores priors and posteriors as well as the actual rectangleGate.

fcTree	*constructor of* fcTree

Description

It adds an extra node data slot "fList"(which is a filterList object) to the gatingTemplate

Usage

```
fcTree(gt)
```

Arguments

gt	a gatingTemplate object

fcTree-class	*A class to represent a flowClust tree.*

Description

It is a graphNEL used as a container to store priors and posteriors for each flowClust gate that can be visualized for the purpose of fine-tunning parameters for flowClust algorithm

gate_flowClust_1d   *Applies flowClust to 1 feature to determine a cutpoint between the min-*
                         imum cluster and all other clusters.

Description

We cluster the observations in `fr` into `K` clusters.

Usage

```
gate_flowClust_1d(fr, params, filterId = "", K = NULL, trans = 0,
  min.count = -1, max.count = -1, nstart = 1, prior = NULL,
  criterion = c("BIC", "ICL"), cutpoint_method = c("boundary",
  "min_density", "quantile", "posterior_mean", "prior_density"),
  neg_cluster = 1, cutpoint_min = NULL, cutpoint_max = NULL, min = NULL,
  max = NULL, quantile = 0.99, quantile_interval = c(0, 10),
  plot = FALSE, debug = FALSE, ...)

flowClust.1d(fr, params, filterId = "", K = NULL, trans = 0,
  min.count = -1, max.count = -1, nstart = 1, prior = NULL,
  criterion = c("BIC", "ICL"), cutpoint_method = c("boundary",
  "min_density", "quantile", "posterior_mean", "prior_density"),
  neg_cluster = 1, cutpoint_min = NULL, cutpoint_max = NULL, min = NULL,
  max = NULL, quantile = 0.99, quantile_interval = c(0, 10),
  plot = FALSE, debug = FALSE, ...)
```

Arguments

fr	a flowFrame object
params	character channel to be gated on
filterId	A character string that identifies the filter created.
K	the number of clusters to find
trans, min.count, max.count, nstart	
	some flowClust parameters. see [flowClust]
prior	list of prior parameters for the Bayesian [flowClust]. If NULL, no prior is used.
criterion	a character string stating the criterion used to choose the best model. May take either "BIC" or "ICL". This argument is only relevant when K is NULL or if length(K) > 1. The value selected is passed to [flowClust].
cutpoint_method	
	How should the cutpoint be chosen from the fitted [flowClust] model? See Details.
neg_cluster	integer. The index of the negative cluster. The cutpoint is computed between clusters neg_cluster and neg_cluster + 1.
cutpoint_min	numeric value that sets a minimum thresold for the cutpoint. If a value is provided, any cutpoint below this value will be set to the given minimum value. If NULL (default), there is no minimum cutpoint value.
cutpoint_max	numeric value that sets a maximum thresold for the cutpoint. If a value is provided, any cutpoint above this value will be set to the given maximum value. If NULL (default), there is no maximum cutpoint value.

min	a numeric value that sets the lower bound for data filtering. If NULL (default), no truncation is applied.
max	a numeric value that sets the upper bound for data filtering. If NULL (default), no truncation is applied.
quantile	the quantile for which we will find the cutpoint using the quantile `cutpoint_method`. If the `cutpoint_method` is not set to `quantile`, this argument is ignored.
quantile_interval	
	a vector of length 2 containing the end-points of the interval of values to find the quantile cutpoint. If the `cutpoint_method` is not set to `quantile`, this argument is ignored.
plot	logical value indicating that the fitted [flowClust](#) model should be plotted along with the cutpoint
debug	`logical` indicating whether to carry the prior and posterious with the gate for debugging purpose. Default is FALSE.
...	additional arguments that are passed to [flowClust](#)

Details

By default, the cutpoint is chosen to be the boundary of the first two clusters. That is, between the first two cluster centroids, we find the midpoint between the largest observation from the first cluster and the smallest observations from the second cluster. Alternatively, if the `cutpoint_method` is `min_density`, then the cutpoint is the point at which the density between the first and second smallest cluster centroids is minimum.

Value

a `rectangleGate` object consisting of all values beyond the cutpoint calculated

Examples

```
## Not run:
 gate <- gate_flowClust_1d(fr, params = "APC-A", K =2) # fr is a flowFrame

## End(Not run)
```

---

gate_flowClust_2d	*Automatic identification of a population of interest via flowClust based on two markers*

Description

We cluster the observations in `fr` into K clusters. We set the cutpoint to be the point at which the density between the first and second smallest cluster centroids is minimum.

Usage

```
gate_flowClust_2d(fr, xChannel, yChannel, filterId = "", K = 2,
  usePrior = "no", prior = list(NA), trans = 0, min.count = -1,
  max.count = -1, nstart = 1, plot = FALSE, target = NULL,
  transitional = FALSE, quantile = 0.9, translation = 0.25,
  transitional_angle = NULL, min = NULL, max = NULL, ...)

flowClust.2d(fr, xChannel, yChannel, filterId = "", K = 2,
  usePrior = "no", prior = list(NA), trans = 0, min.count = -1,
  max.count = -1, nstart = 1, plot = FALSE, target = NULL,
  transitional = FALSE, quantile = 0.9, translation = 0.25,
  transitional_angle = NULL, min = NULL, max = NULL, ...)
```

Arguments

`fr`	a flowFrame object
`xChannel, yChannel`	
	character specifying channels to be gated on
`filterId`	A character string that identifies the filter created.
`K`	the number of clusters to find
`usePrior`	Should we use the Bayesian version of [flowClust](#)? Answers are "yes", "no", or "vague". The answer is passed along to [flowClust](#).
`prior`	list of prior parameters for the Bayesian version of [flowClust](#). If usePrior is set to no, then the list is unused.
`trans, min.count, max.count, nstart`	
	some flowClust parameters. see [flowClust](#)
`plot`	a logical value indicating if the fitted mixture model should be plotted. By default, no.
`target`	a numeric vector of length 2 (number of dimensions) containing the location of the cluster of interest. See details.
`transitional`	logical value indicating if a transitional gate should be constructed from the target [flowClust](#) cluster. By default, no.
`quantile`	the contour level of the target cluster from the [flowClust](#) fit to construct the gate
`translation`	a numeric value between 0 and 1 used to position a transitional gate if `transitional = TRUE`. This argument is ignored if `transitional = FALSE`. See details
`transitional_angle`	
	the angle (in radians) of the transitional gate. It is also used to determine which quadrant the final gate resides in. See details. Ignored if `transitional = FALSE`.
`min`	A vector of length 2. Truncate observations less than this minimum value. The first value truncates the xChannel, and the second value truncates the yChannel. By default, this vector is NULL and is ignored.
`max`	A vector of length 2. Truncate observations greater than this maximum value. The first value truncates the xChannel, and the second value truncates the yChannel. By default, this vector is NULL and is ignored.
`...`	additional arguments that are passed to [flowClust](#)

Details

The cluster for the population of interest is selected as the one with cluster centroid nearest the `target` in Euclidean distance. By default, the largest cluster (i.e., the cluster with the largest proportion of observations) is selected as the population of interest.

We also provide the option of constructing a `transitional` gate from the selected population of interest. The location of the gate can be controlled with the `translation` argument, which translates the gate along the major axis of the targest cluster as a function of the appropriate chi-squared coefficient. The larger `translation` is, the more gate is shifted in a positive direction. Furthermore, the width of the `transitional` gate can be controlled with the `quantile` argument.

The direction of the transitional gate can be controlled with the `transitional_angle` argument. By default, it is NULL, and we use the eigenvector of the `target` cluster that points towards the first quadrant (has positive slope). If `transitional_angle` is specified, we rotate the eigenvectors so that the angle between the x-axis (with the cluster centroid as the origin) and the major eigenvector (i.e., the eigenvector with the larger eigenvalue) is `transitional_angle`. So based on range that the angle falls in, the final rectangleGate will be constructed at the corresponding quadrant. i.e. Clockwise, [0,pi/2] UR, (pi/2, pi] LR, (pi, 3/2 * pi] LL, (3/2 * pi, 2 * pi] UL

Value

a `polygonGate` object containing the contour (ellipse) for 2D gating.

Examples

```
## Not run:
 gate <- gate_flowClust_2d(fr, xChannel = "FSC-A", xChannel = "SSC-A", K = 3) # fr is a flowFrame

## End(Not run)
```

---

gate_mindensity	*Determines a cutpoint as the minimum point of a kernel density estimate between two peaks*

Description

We fit a kernel density estimator to the cells in the `flowFrame` and identify the two largest peaks. We then select as the cutpoint the value at which the minimum density is attained between the two peaks of interest.

Usage

```
gate_mindensity(fr, channel, filterId = "", positive = TRUE,
  pivot = FALSE, gate_range = NULL, min = NULL, max = NULL,
  peaks = NULL, ...)

mindensity(fr, channel, filterId = "", positive = TRUE, pivot = FALSE,
  gate_range = NULL, min = NULL, max = NULL, peaks = NULL, ...)
```

Arguments

`fr`	a `flowFrame` object
`channel`	TODO
`filterId`	TODO
`positive`	If `TRUE`, then the gate consists of the entire real line to the right of the cutpoint. Otherwise, the gate is the entire real line to the left of the cutpoint. (Default: `TRUE`)
`pivot`	logical value. If `TRUE`, we choose as the two peaks the largest peak and its neighboring peak. See details.
`gate_range`	numeric vector of length 2. If given, this sets the bounds on the gate applied. If no gate is found within this range, we set the gate to the minimum value within this range if `positive` is `TRUE` and the maximum value of the range otherwise.
`min`	a numeric value that sets the lower boundary for data filtering
`max`	a numeric value that sets the upper boundary for data filtering
`peaks`	`numeric` vector. If not given , then perform peak detection first by .find_peaks
`...`	Additional arguments for peak detection.

Details

In the default case, the two peaks of interest are the two largest peaks obtained from the `link{density}` function. However, if `pivot` is `TRUE`, we choose the largest peak and its neighboring peak as the two peaks of interest. In this case, the neighboring peak is the peak immediately to the left of the largest peak if `positive` is `TRUE`. Otherwise, the neighboring peak is selected as the peak to the right.

In the special case that there is only one peak, we are conservative and set the cutpoint as the `min(x)` if `positive` is `TRUE`, and the `max(x)` otherwise.

Value

a `rectangleGate` object based on the minimum density cutpoint

Examples

```
## Not run:
 gate <- gate_mindensity(fr, channel = "APC-A") # fr is a flowFrame

## End(Not run)
```

---

gate_mindensity2	*An improved version of mindensity used to determines a cutpoint as the minimum point of a kernel density estimate between two peaks.*

Description

Analogous to the original openCyto::mindensity(), mindensity2 operates on a standard flowFrame. Its behavior is closely modeled on the original mindensity() whenever possible. However, the underlying peak-finding algorithm (improvedMindensity) behaves significantly differently.

Usage

```
gate_mindensity2(fr, channel, filterId = "", pivot = FALSE,
  gate_range = NULL, min = NULL, max = NULL, peaks = NULL, ...)

mindensity2(fr, channel, filterId = "", pivot = FALSE, gate_range = NULL,
  min = NULL, max = NULL, peaks = NULL, ...)
```

Arguments

fr	a flowFrame object
channel	the channel to operate on
filterId	a name to refer to this filter
pivot	logical value. If TRUE, we choose as the two peaks the largest peak and its neighboring peak. See details.
gate_range	numeric vector of length 2. If given, this sets the bounds on the gate applied.
min	a numeric value that sets the lower boundary for data filtering
max	a numeric value that sets the upper boundary for data filtering
peaks	numeric vector. If not given , then perform peak detection first by .find_peaks
...	Additional arguments for peak detection.

Value

a rectangleGate object based on the minimum density cutpoint

Author(s)

Greg Finak, Phu T. Van

Examples

```
## Not run:
 gate <- gate_mindensity2(fr, channel = "APC-A") # fr is a flowFrame

## End(Not run)
```

---

gate_quad_sequential   *sequential quadrant gating function*

Description

The order of 1d-gating is determined so that the gates better capture the distributions of flow data.

Usage

```
gate_quad_sequential(fr, channels, gFunc, min = NULL, max = NULL, ...)

quadGate.seq(fr, channels, gFunc, min = NULL, max = NULL, ...)
```

Arguments

`fr`	flowFrame
`channels`	character two channels used for gating
`gFunc`	the name of the 1d-gating function to be used for either dimension
`min`	a numeric vector that sets the lower bounds for data filtering
`max`	a numeric vector that sets the upper bounds for data filtering
`...`	other arguments passed to `.find_peak` (e.g. 'num_peaks' and 'adjust'). see [tailgate](#)

Value

a `filters` that contains four rectangleGates

`gate_quad_tmix`	*quadGate based on flowClust::tmixFiler*

Description

This gating method identifies two quadrants (first, and third quadrants) by fitting the data with tmixture model. It is particularly useful when the two markers are not well resolved thus the regular quadGate method based on 1d gating will not find the perfect cut points on both dimensions.

Usage

```
gate_quad_tmix(fr, channels, K, usePrior = "no", prior = list(NA),
  quantile1 = 0.8, quantile3 = 0.8, trans = 0, plot = FALSE, ...)

quadGate.tmix(fr, channels, K, usePrior = "no", prior = list(NA),
  quantile1 = 0.8, quantile3 = 0.8, trans = 0, plot = FALSE, ...)
```

Arguments

`fr`	flowFrame
`channels`	character vector specifies two channels
`K`	see [flowClust.2d](#)
`usePrior`	see [flowClust.2d](#)
`prior`	see [flowClust.2d](#)
`quantile1`	numeric specifies the quantile level(see 'level' in [flowClust](#)) for the first quadrant (x-y+)
`quantile3`	numeric specifies the quantile level see 'level' in [flowClust](#) for third quadrant (x+y-)
`trans`	see [flowClust.2d](#)
`plot`	logical whether to plot flowClust clustering results
`...`	other arguments passed to [flowClust](#)

Value

a `filters` object that contains four polygonGates following the order of (-+,++,+-,--)

---

gate_quantile *Determine the cutpoint by the events quantile.*

Description

It is possible that the cutpoint calculated by quantile function may not produce the exact the probability set by 'probs' argument if there are not enough cell events to reach that precision. Sometime the difference could be significant.

Usage

```
gate_quantile(fr, channel, probs = 0.999, plot = FALSE, filterId = "",
  min = NULL, max = NULL, ...)

quantileGate(fr, channel, probs = 0.999, plot = FALSE, filterId = "",
  min = NULL, max = NULL, ...)
```

Arguments

fr	a flowFrame object
channel	the channel from which the cytokine gate is constructed
probs	probabilities passed to 'stats::quantile' function.
plot	whether to plot the gate result
filterId	the name of the filter
min	a numeric value that sets the lower boundary for data filtering
max	a numeric value that sets the upper boundary for data filtering
...	additional arguments passed to 'stats::quantile' function.

Value

a rectangleGate

Examples

```
## Not run:
 gate <- gate_quantile(fr, Channel = "APC-A", probs = 0.995) # fr is a flowFrame

## End(Not run)
```

gate_tail	*Gates the tail of a density using the derivative of a kernel density esti-mate*

Description

Gates the tail of a density using the derivative of a kernel density estimate

Usage

```
gate_tail(fr, channel, filterId = "", num_peaks = 1, ref_peak = 1,
  strict = TRUE, tol = 0.01, side = "right", min = NULL, max = NULL,
  bias = 0, ...)

tailgate(fr, channel, filterId = "", num_peaks = 1, ref_peak = 1,
  strict = TRUE, tol = 0.01, side = "right", min = NULL, max = NULL,
  bias = 0, ...)

cytokine(fr, channel, filterId = "", num_peaks = 1, ref_peak = 1,
  tol = 0.01, side = "right", ...)
```

Arguments

fr	a flowFrame object
channel	the channel from which the cytokine gate is constructed
filterId	the name of the filter
num_peaks	the number of peaks expected to see. This effectively removes any peaks that are artifacts of smoothing
ref_peak	After num_peaks are found, this argument provides the index of the reference population from which a gate will be obtained.
strict	logical when the actual number of peaks detected is less than ref_peak. an error is reported by default. But if strict is set to FALSE, then the reference peak will be reset to the peak of the far right.
tol	the tolerance value used to construct the cytokine gate from the derivative of the kernel density estimate
side	On which side of the density do we want to gate the tail, the 'right' (default) or 'left'?
min	a numeric value that sets the lower boundary for data filtering
max	a numeric value that sets the upper boundary for data filtering
bias	a numeric value that adds a constant to the calculated cutpoint(threshold). Default is 0.
...	additional arguments.

Value

a filterList containing the gates (cutpoints) for each sample

Examples

```
## Not run:
 gate <- gate_tail(fr, Channel = "APC-A") # fr is a flowFrame

## End(Not run)
```

---

gating	*Apply the gates to a GatingSet*

Description

It applies the gates to the GatingSet based on the population tree described in graphGML.

It loads the gating methods by topological order and applies them to `GatingSet`.

Usage

```
gating(x, y, ...)

## S4 method for signature 'gatingTemplate,GatingSet'
gating(x, y, env_fct = NULL, ...)

## S4 method for signature 'gatingTemplate,GatingSetList'
gating(x, y, env_fct = NULL, ...)

## S4 method for signature 'boolMethod,GatingSet'
gating(x, y, ...)

## S4 method for signature 'polyFunctions,GatingSet'
gating(x, y, ...)

## S4 method for signature 'refGate,GatingSet'
gating(x, y, ...)
```

Arguments

x	a `gatingTemplate` object
y	a `GatingSet` object
...	• start a `character` that specifies the population (correspoding to 'alias' column in csv template) where the gating process will start from. It is useful to quickly skip some gates and go directly to the target population in the testing run. Default is "root".
	• stop.at a `character` that specifies the population (correspoding to 'alias' column in csv template) where the gating prcoess will stop at. Default is NULL, indicating the end of gating tree.
	• keep.helperGatesa `logical` flag indicating whether to keep the intermediate helper gates that are automatically generated by openCyto. Default is TRUE.
	• mc.cores passed to `multicore` package for parallel computing
	• parallel_type `character` specifying the parallel type. The valid options are "none", "multicore", "cluster".

- cl cluster object passed to `parallel` package (when `parallel_type` is "cluster")

env_fct   a environment that contains fcTree object named as 'fct'. If NULL (by default), no `fcTree` will be constructed. It is currently reserved for the internal debugging.

Value

Nothing. As the side effect, gates generated by gating methods are saved in `GatingSet`.

Examples

```
## Not run:
 gt <- gatingTemplate(file.path(path, "data/ICStemplate.csv"), "ICS")
 gs <- GatingSet(fs) #fs is a flowSet/ncdfFlowSet
 gating(gt, gs)
 gating(gt, gs, stop.at = "v") #proceed the gating until population 'v'
 gating(gt, gs, start = "v") # start from 'v'
 gating(gt, gs, parallel_type = "multicore", mc.cores = 8) #parallel gating using multicore
 #parallel gating by using cluster
 cl1 <- makeCluster (8, type = "MPI")
 gating(gt, gs, parallel_type = "cluster", cl = cl1)
 stopCluster ( cl1 )

## End(Not run)
```

---

gating,gtMethod,GatingSet-method
                        apply a [gtMethod](#) to the GatingSet

---

Description

apply a [gtMethod](#) to the `GatingSet`

Usage

```
## S4 method for signature 'gtMethod,GatingSet'
gating(x, y, ...)
```

Arguments

x   gtMethod

y   GatingSet

...   other arguments

gatingTemplate-class   *a class storing the gating method and population information in a graphNEL object*

Description

Each cell population is stored in graph node and is connected with its parent population or its reference node for boolGate or refGate.

It parses the csv file that specifies the gating scheme for a particular staining pannel.

Usage

```
gatingTemplate(x, ...)

## S4 method for signature 'character'
gatingTemplate(x, name = "default", strict = TRUE,
  strip_extra_quotes = FALSE, ...)
```

Arguments

x	character csv file name
...	other arguments passed to `data.table::fread`
name	character the label of the gating template
strict	logical whether to perform validity check(special characters) on the alias column. By default it is(and should be) turned on for the regular template parsing. But sometime it is useful to turned it off to bypass the check for the dummy nodes(e.g. the csv template generated by 'templateGen' with some existing boolean gates that has '!' or ':' symbol).
strip_extra_quotes	
	logical Extra quotes are added to strings by fread. This causes problems with parsing R strings to expressions in some cases. Default FALSE for usual behaviour. TRUE should be passed if parsing gating_args fails.

Details

This csv must have the following columns:

'alias': a name used label the cell population, the path composed by the alias and its precedent nodes (e.g. /root/A/B/alias) has to be uniquely identifiable. So alias can not contain '/' character, which is reserved as path delimiter.

'pop': population patterns of '+/-' or '+/-+/-', which tells the algorithm which side (postive or negative) of 1d gate or which quadrant of 2d gate to be kept.

'parent': the parent population alias, its path has to be uniquely identifiable.

'dims': characters seperated by comma specifying the dimensions(1d or 2d) used for gating. It can be either channel name or stained marker name (or the substrings of channel/marker names as long as they are uniquely identifiable.).

'gating_method': the name of the gating function (e.g. 'flowClust'). It is invoked by a wrapper function that has the identical function name prefixed with a dot.(e.g. '.flowClust')

'gating_args': the named arguments passed to gating function (Note that double quotes are often used as text delimiter by some csv editors. So try to use single quote instead if needed.)

'collapseDataForGating': When TRUE, data is collapsed (within groups if 'groupBy' specified) before gating and the gate is replicated across collapsed samples. When set FALSE (or blank),then 'groupBy' argument is only used by 'preprocessing' and ignored by gating.

'groupBy': If given, samples are split into groups by the unique combinations of study variable (i.e. column names of pData,e.g."PTID:VISITNO"). when split is numeric, then samples are grouped by every N samples

'preprocessing_method': the name of the preprocessing function(e.g. 'prior_flowClust'). It is invoked by a wrapper function that has the identical function name prefixed with a dot.(e.g. '.prior_flowClust') the preprocessing results are then passed to gating wrapper function through 'pps_res' argument.

'preprocessing_args': the named arguments passed to preprocessing function.

Examples

```
## Not run:
  gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
  plot(gt)

## End(Not run)
```

```
getChildren,gatingTemplate,character-method
```
get children nodes

Description

get children nodes

Usage

```
## S4 method for signature 'gatingTemplate,character'
getChildren(obj, y)
```

Arguments

obj	gatingTemplate
y	character parent node path

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))

getNodes(gt, "/nonDebris")
getChildren(gt, "/nonDebris")

## End(Not run)
```

```
getGate,fcTree,character-method
```
get gates saved in fcTree

Description

get gates saved in fcTree

Usage

```
## S4 method for signature 'fcTree,character'
getGate(obj, y, ...)
```

Arguments

obj	fcTree
y	character node name
...	other arguments (not used)

```
getGate,gatingTemplate,character-method
```
get gating method from the node

Description

get gating method from the node

Usage

```
## S4 method for signature 'gatingTemplate,character'
getGate(obj, y, z)
```

Arguments

obj	gatingTemplate
y	character parent node path
z	character child node path

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
getNodes(gt, only.names = TRUE)
getNodes(gt, "/nonDebris")
getChildren(gt, "/nonDebris")
getGate(gt, "/nonDebris", "/nonDebris/singlets")

## End(Not run)
```

```
getNodes,fcTree-method
```
get nodes from fcTree

Description

get nodes from fcTree

Usage

```
## S4 method for signature 'fcTree'
getNodes(x, y)
```

Arguments

x	fcTree
y	character node name

```
getNodes,gatingTemplate-method
```
get nodes from gatingTemplate object

Description

get nodes from gatingTemplate object

Usage

```
## S4 method for signature 'gatingTemplate'
getNodes(x, y, order = c("default", "bfs", "dfs",
  "tsort"), only.names = FALSE)
```

Arguments

x	gatingTemplate
y	character node index. When missing, return all the nodes
order	character specifying the order of nodes. options are "default", "bfs", "dfs", "tsort"
only.names	logical specifiying whether user wants to get the entire gtPopulation object or just the name of the population node

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
getNodes(gt)[1:2]
getNodes(gt, only.names = TRUE)
getNodes(gt, "/nonDebris")

## End(Not run)
```

getParent,gatingTemplate,character-method
get parent nodes

Description

get parent nodes

Usage

```
## S4 method for signature 'gatingTemplate,character'
getParent(obj, y, isRef = FALSE)
```

Arguments

obj	gatingTemplate
y	character child node path
isRef	logical whether show the reference node besides the parent node

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))

getNodes(gt, "/nonDebris")
getParent(gt, "/nonDebris/singlets")

## End(Not run)
```

groupBy,gtMethod-method
get the grouping variable for the gating method

Description

When specified, the flow data is grouped by the grouping variable (column names in pData). Within each group, when isCollapse is set to TRUE, the gating method is applied to the collapsed data. Otherwise, it is done indepently for each indiviudal sample(flowFrame). Grouping variable is also used by preprocessing method.

Usage

```
## S4 method for signature 'gtMethod'
groupBy(object)
```

Arguments

object	gtMethod

---

gtMethod-class   *A class to represent a gating method.*

Description

A gating method object contains the specifics for generating the gates.

Slots

name a `character` specifying the name of the gating method

dims a `character` vector specifying the dimensions (channels or markers) of the gate

args a `list` specifying the arguments passed to gating function

groupBy a `character` or `integer` specifying how to group the data if `character`,group the data by the study variables (columns in `pData`) if `integer`, group the data by every N samples.

collapse a `logical` specifying wether to collapse the data within group before gating. it is only valid when `groupBy` is specified

Examples

```
## Not run:
   gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
    getGate(gt, '2', '3')

## End(Not run)
```

---

gtPopulation-class   *A class to represent a cell population that will be generated by a gating method.*

Description

A class to represent a cell population that will be generated by a gating method.

Slots

id `numeric` unique ID that is consistent with node label of graphNEL in gating template

name `character` the name of population

alias `character` the more user friendly name of population

Examples

```
## Not run:
   gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))

     getNodes(gt, '2')

## End(Not run)
```

---

gtSubsets-class *A class representing a group of cell populations.*

Description

It extends `gtPopulation` class.

---

isCollapse,gtMethod-method

get the flag that determines whether gating method is applied on collapsed data

---

Description

When TRUE, the flow data(multiple flowFrames) is collapsed into one and the gating method is applied on the collapsed data. Once the gate is generated, it is thenreplicated and applied to the each single flowFrame.

Usage

```
## S4 method for signature 'gtMethod'
isCollapse(object)
```

Arguments

object   gtMethod

Value

logical

---

listgtMethods *Print a list of the registered gating methods*

Description

Print a list of the registered gating methods

Usage

```
listgtMethods()
```

Value

Does not return anything. Prints a list of the available gating methods.

names,gtMethod-method   *get gating method name*

Description

get gating method name

Usage

```
## S4 method for signature 'gtMethod'
names(x)
```

Arguments

x   gtMethod

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))

gtMthd <- getGate(gt, "/nonDebris/singlets",  "/nonDebris/singlets/lymph")
names(gtMthd)
dims(gtMthd)
parameters(gtMthd)
isCollapse(gtMthd)
groupBy(gtMthd)

gtPop <- getNodes(gt, "/nonDebris/singlets/lymph/cd3/cd4+cd8-/CD38+")
names(gtPop)
alias(gtPop)

## End(Not run)
```

names,gtPopulation-method
                              get population name

Description

get population name

Usage

```
## S4 method for signature 'gtPopulation'
names(x)
```

Arguments

x   gtPopulation object

---

ocRectangleGate-class   *the class that carries event indices as well*

Description

the class that carries event indices as well

---

ocRectRefGate   *constructor for ocRectRefGate*

Description

constructor for ocRectRefGate

Usage

```
ocRectRefGate(rectGate, boolExprs)
```

Arguments

rectGate   rectangleGate

boolExprs   character boolean expression of reference nodes

---

ocRectRefGate-class   *special gate type that mix the rectangleGate with boolean gate*

Description

special gate type that mix the rectangleGate with boolean gate

---

openCyto   *Hierarchical Gating Pipeline for flow cytometry data*

Description

Hierarchical Gating Pipeline for flow cytometry data.

Details

openCyto is a package designed to facilitate the automated gating methods in sequential way to mimic the manual gating strategy.

Package:	openCyto
Type:	Package
Version:	1.2.8
Date:	2014-04-10
License:	GPL (>= 2)
LazyLoad:	yes

Author(s)

Mike Jiang <wjiang2@fhcrc.org>, John Ramey <jramey@fhcrc.org>, Greg Finak <gfinak@fhcrc.org>

Maintainer: Mike Jiang <wjiang2@fhcrc.org>

See Also

See [gating](#), [flowClust.1d](#), for an overview of gating functions.

Examples

```
## Not run: gatingTemplate('test.csv')
```

---

openCyto.options	*Some global options for openCyto See examples for the meaning of these options and how to get/set them.*

Description

Get/set some global options for openCyto

Examples

```
opt <- getOption("openCyto")
#the threshold of minimum cell events required for the gating algorithm to proceed
opt[["gating"]][["minEvents"]]
#to change the threshold
opt[["gating"]][["minEvents"]] <- 100
options(openCyto = opt)

#switch off the validity check flags(Not recommended)
opt[["check.pop"]] <- FALSE
options(openCyto = opt)
```

---

parameters,gtMethod-method

get parameters of the gating method/function

Description

get parameters of the gating method/function

Usage

```
## S4 method for signature 'gtMethod'
parameters(object)
```

Arguments

object   gtMethod

plot,fcFilterList,ANY-method
plot a `fcFilterList`

Description

It is usually called by `plot` method for `fcTree` instead of directly by users.

Usage

```
## S4 method for signature 'fcFilterList,ANY'
plot(x, y, samples = NULL, posteriors = FALSE,
  xlim = NULL, ylim = NULL, node = NULL, data = NULL, breaks = 20,
  lwd = 1, ...)
```

Arguments

x	fcFilterList
y	character channel name
samples	character a vector of sample names to be plotted
posteriors	logical indicating whether posteriors should be plotted
xlim, ylim	scale settings for x,y axises
node	character population name associated with the fcFilterList
data	GatingSet object
breaks	passed to hist
lwd	line width
...	other arguments passed to base plot

Examples

```
## Not run:
 env1<-new.env(parent=emptyenv())
 #gt is a gatingTemplate, gs is a GatingSet
 gating(gt,gs,env1) #the flowClust gating results are stored in env1
 plot(env1$fct,"nonDebris",post=T) #plot the priors as well as posteriors for the "nonDebris" gate

## End(Not run)
```

```
plot,fcTree,character-method
```
               plot the flowClust gating results

Description

This provides the priors and posteriors as well as the gates for the purpose of debugging flowClust gating algorithm

Usage

```
## S4 method for signature 'fcTree,character'
plot(x, y, channel = NULL, data = NULL, ...)
```

Arguments

x	fcTree
y	character node name in the fcTree
channel	character specifying the channel.
data	GatingSet that the fcTree is associated with
...	other arguments

```
plot,gatingTemplate,missing-method
```
                    plot the gating scheme

Description

plot the gating scheme using Rgraphviz

Usage

```
## S4 method for signature 'gatingTemplate,missing'
plot(x, y, ...)
```

Arguments

x	gatingTemplate object
y	either character specifying the root node which can be used to visualize only the subgraph or missing which display the entire gating scheme
...	other arguments
	graphAttr, nodeAttr: graph rendering attributes passed to renderGraph showRef logical: whether to display the reference gates. Sometime it maybe helpful to hide all those reference gates which are not the cell population of interest and used primarily for generating other population nodes.

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
plot(gt) #plot entire tree
plot(gt, "lymph") #only plot the subtree rooted from "lymph"

## End(Not run)
```

---

polyFunctions-class   *A class to represent a polyFunctions gating method.*

Description

It extends boolMethod class and will be expanded to multiple boolMethod object.

---

posteriors,fcFilter,ANY-method
                     get posteriors from a fcFilter *object*

Description

get posteriors from a fcFilter object

Usage

```
## S4 method for signature 'fcFilter,ANY'
posteriors(x, y = "missing")
```

Arguments

x   fcFilter

y   character or missing that specifiy which channel to look for

---

ppMethod,gatingTemplate,character-method
                     get preprocessing method from the node

Description

get preprocessing method from the node

Usage

```
## S4 method for signature 'gatingTemplate,character'
ppMethod(obj, y, z)
```

Arguments

obj	gatingTemplate
y	character parent node path
z	character child node path

Examples

```
## Not run:
gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
ppMethod(gt,  "/nonDebris/singlets",  "/nonDebris/singlets/lymph")

## End(Not run)
```

---

ppMethod-class   *A class to represent a preprocessing method.*

Description

It extends gtMethod class.

Examples

```
 ## Not run:
    gt <- gatingTemplate(system.file("extdata/gating_template/tcell.csv",package = "openCyto"))
     ppMethod(gt, '3', '4')

## End(Not run)
```

---

preprocessing,ppMethod,GatingSet-method
                            apply a [ppMethod](#) to the GatingSet

---

Description

apply a [ppMethod](#) to the GatingSet

Usage

```
## S4 method for signature 'ppMethod,GatingSet'
preprocessing(x, y, ...)
```

Arguments

x	ppMethod
y	GatingSet or GatingSetList
...	other arguments

```
priors,fcFilter,ANY-method
```
get priors from a fcFilter *object*

Description

get priors from a fcFilter object

Usage

```
## S4 method for signature 'fcFilter,ANY'
priors(x, y = "missing")
```

Arguments

x   fcFilter object

y   character specifying channel name. if missing then extract priors for all the
                channels

```
prior_flowClust          Elicits data-driven priors from a flowSet object for specified channels
```

Description

We elicit data-driven prior parameters from a flowSet object for specified channels. For each
sample in the flowSet object, we apply the given prior_method to elicit the priors parameters.

Usage

```
prior_flowClust(flow_set, channels, prior_method = c("kmeans"), K = 2,
  nu0 = 4, w0 = c(10, 10), shrink = 1e-06, ...)
```

Arguments

flow_set   a flowSet object

channels   a character vector containing the channels in the flowSet from which we elicit
                the prior parameters for the Student's t mixture

prior_method   the method to elicit the prior parameters

K   the number of mixture components to identify

nu0   prior degrees of freedom of the Student's t mixture components.

w0   the number of prior pseudocounts of the Student's t mixture components. (only
                the first element is used and the rest is ignored at the moment)

shrink   the amount of eigenvalue shrinkage to add in the case the prior covariance ma-
                trices are singular. See details.

...   Additional arguments passed to the prior elicitation method selected

Details

Currently, we have implemented only two methods. In the case that one channel is given, we use the kernel-density estimator (KDE) approach for each sample to obtain K peaks from which we elicit prior parameters. Otherwise, if more than one channel is specified, we apply K-Means to each of the samples in the `flowSet` and aggregate the clusters to elicit the prior parameters.

In the rare case that a prior covariance matrix is singular, we shrink the eigenvalues of the matrix slightly to ensure that it is positive definite. For instance, if the `flow_set` has two samples, this case can occur. The amount of shrinkage is controlled in `shrink`.

Value

list of the necessary prior parameters

---

refGate-class   *A class to represent a reference gating method.*

Description

It extends `gtMethod` class.

Slots

refNodes `character` specifying the reference nodes

---

registerPlugins   *Register a gating or preprocessing function with OpenCyto*

Description

Function registers a new gating or preprocessing method with openCyto so that it may be used in the csv template.

Usage

```
registerPlugins(fun = NA, methodName, dep = NA, ...)
```

Arguments

fun	function to be registered
methodName	character name of the gating or preprocessing method
dep	character name of the library dependency required for the plugin method to work.
...	other arguments type `character` specifying the type of registering method. Should be either "gating" or "preprocessing".

Details

The `fun` argument should be a wrapper function definition for the gating or preprocessing method. Gating method must have formal arguments:

fr a `flowFrame`

pp_res a pre-processing result

xChannel character (optional)

yChannel character (required)

filterId `character`

... ellipses for the additional parameters.

Preprocessing method must have formal arguments:

fs a `flowSet` that stores the flow data (could be subgrouped data if `groupBy` column is defined in the csv template

gs a `GatingSet`

gm a `gtMethod` object that stores the information from gating method

xChannel character (required)

yChannel character (required)

... ellipses for the additional parameters.

The gating function must return a filter (i.e. polygonGate or other instance) from flowCore. The preprocessing can return anything and it will be passed on to the gating function. So it is up to gating function to use and interpret the results of preprocessing. Not all formal parameters need to be used. Additional arguments are passed via the ... and can be processed in the wrapper

Value

`logical` TRUE if successful and prints a message. FALSE otherwise.

---

show,boolMethod-method
show method for boolMethod

Description

show method for boolMethod

Usage

```
## S4 method for signature 'boolMethod'
show(object)
```

Arguments

object   boolMethod

---

show,fcFilter-method   *show method for fcFilter*

Description

show method for fcFilter

Usage

```
## S4 method for signature 'fcFilter'
show(object)
```

Arguments

object   fcFilter show method for fcFilter

---

show,gatingTemplate-method
                    show method for gatingTemplate

Description

show method for gatingTemplate

Usage

```
## S4 method for signature 'gatingTemplate'
show(object)
```

Arguments

object   gatingTemplate

---

show,gtMethod-method   *show method for gtMethod*

Description

show method for gtMethod

Usage

```
## S4 method for signature 'gtMethod'
show(object)
```

Arguments

object   gtMethod show method for gtMethod

templateGen	*generate a partially complete csv template from the existing gating hierarchy*

Description

To ease the process of replicating the existing (usually a manual one) gating schemes, this function populate an empty gating template with the 'alias', 'pop', 'parent' and 'dims' columns that exacted from an `GatingHierarchy`, and leave the other columns (e.g. 'gating_method') blank. So users can make changes to that template instead of writing from scratch.

Usage

```
templateGen(gh)
```

Arguments

gh   a `GatingHierarchy` likely parsed from a xml workspace

Value

a gating template in `data.frame` format that requires further edition after output to csv

toggle.helperGates	*toggle/delete the hidden flag of the helper gates*

Description

The helper gates are defined as the referred gates in csv template. And all the chidlren of referred gates are also referred gates thus they are considered the helper gates and can usually be hidden to simply the final gating tree.

Usage

```
toggle.helperGates(gt, gs)

get.helperGates(gt, gs)

delete.helperGates(gt, gs)
```

Arguments

gt   gatingTemplate object
gs   GatingSet

Details

Note that delete action is NOT reversible.

Examples

```
## Not run:
gt <- gatingTemplate(gtFile)
#run the gating
gating(gt, gs)
#hide the gates that are not of interest
toggle.helperGates(gt, gs)
#or simply remove them if you are sure they will not be useful in future
delete.helperGates(gt, gs)

## End(Not run)
```
